So far as œdema is concerned, and the transfer of fluids and dissolved substances into and out of the cells of living matter, Dr. Fischer criticises very severely the "osmotic theory," which attempts to explain the observed phenomena by appealing to differences in the osmotic pressures exerted by the contents of the cells and by their surroundings. He similarly criticises the "lipoid membrane theory," which endeavours to help out the osmotic theory by assuming that there is a lipoid skin outside each cell to act as a semi-permeable membrane, and to regulate the direction and intensity of the osmosis. In the place of these theories he gives us (1) "the laws of equilibrium" between the contents of the cell and the medium surrounding it (p. 171), these "laws" being influenced by (2) solubility characteristics, (3) phenomena of adsorption, and (4) chemical combination. Armed with these weapons, he finds no difficulty in explaining processes such as the secretion of urine by the kidney, or the excretion of acid gastric juice from the practically neutral blood. The chemistry and physics of colloid solutions and suspensions have made great progress during the present century, and so has the study of the phenomena of adsorption. But surely Dr. Fischer is going rather far when he asks us to believe that the excretion of urine is satisfactorily explained on the following lines (p. 326): "When now we recall the physico-chemical fact that when any dissolved substance is offered simultaneously a liquid colloid, a solid colloid, and water (as is the case in the kidney), an *unequal* distribution of the dissolved substance between the three phases is the *rule*, then we will have no difficulty in understanding why a difference in quantitative composition between the blood, kidney tissue, and urine, so far as dissolved substances are concerned, is also the rule. *Wherefore a 'selective' secretion is to be expected rather than to be wondered at.*" No better instance of an explanation of an *ignotum per ignotius* could be looked for; for what do we know, apart from guess-work, of the physics and chemistry of that incredibly complex fluid, the circulating blood, and what do we know of the physics and chemistry of the living cells that secrete urine in the kidney? How can it be legitimate to describe the blood simply as "a liquid colloid" and the renal cells as "a solid colloid," and further to describe both the blood and the urine as "water"? Given such variables and unknowns as the blood, the renal cells, and the colloids of the body with their variable capacities for attracting water, it is quite easy to speculate on the ways in which urinary secretion and œdema might be produced, without considering the influence that must be exerted by the osmotic pressures of the various crystalloids and colloids entering into the composition of the fluids and cells concerned. But speculations as to the *modus operandi* of these complex processes, valuable though they may be as analogies, can have little finality so long as our knowledge of the special colloids concerned and of the laws of adsorption and colloid chemistry remains as fragmentary as it is at the present time.

In his anxiety to make out a case for the colloids of the body Dr. Fischer appears at times to be in danger of neglecting the crystalloids with which they are inextricably bound up. In speaking of the "variable capacity of the body colloids for holding water," he leaves the reader in some little doubt as to the way in which this water is held. Dr. Fischer compares it to the avidity of fibrin, gelatin, catgut, or the protein of dialysed blood serum for water, and quotes a number of interesting experiments to exhibit the influence of acids, alkalies, and other substances on this avidity. Yet the reader cannot but remember that none of these experimental materials exist in the human body during life, and so may hesitate to agree with Dr. Fischer that "the absorption of water by muscle is determined in the main by the state of the colloids contained in it" (p. 126). Argument by analogy is not a very sound method nor very convincing when the questions at issue are so many and so complex.

Regarding œdema as "a problem in colloid-chemistry" on the lines indicated above, Dr. Fischer will have nothing to do with explanations of it based on "increased permeability of the blood-vessel walls," "decreased ability to hold back water," "increased imbibition," or "variations in blood- or lymph-pressure," time-honoured phrases of an older day. He then quotes (p. 178) a simple experiment which proves clearly that œdema may be due to the tissues' "decreased ability to hold back water," or to their "increased imbibition"; but, oddly enough, he only draws a most illogical conclusion from the experiment himself—namely, that as the vessels of a limb that developed œdema had been tied, circulation-pressures cannot be one of the determining causes of œdema. He gives reasons for believing that an accumulation of acids in the tissues is the most potent factor in the production of œdema, and that this over-production or over-accumulation of acids is often due to a lack of oxygen in the tissues.

About 250 pages of the volume are given to the subject of nephritis. Dr. Fischer recognises only one kind of nephritis—namely, parenchymatous nephritis; but this, he says, may affect either the whole kidney or only spots in it. Speaking generally, he sets nephritis down to the abnormal production or accumulation of acid and of substances which in their action upon colloids behave like acid in the cells of the kidney. Pathologists who are not satisfied with any of the many classifications of the varieties of nephritis should welcome such simplicist conceptions as these. They lead Dr. Fischer to interesting conclusions as to the treatment of chronic nephritis. He supports the use of the "lacto-vegetarian" diet so long advocated by the French, his formula being "give alkali, salts, water, and dextrose"; without making drastic restrictions in the dietary he would cut down the acid-producing proteins of the food. Plenty of water should be given; Dr. Fischer believes that the primary function of the kidney is to excrete water, and that "the secretion of all dissolved substances is secondary to this." He has a number of observations to make on methods of estimating clinically the acidity of the urine, and the deductions that may fairly be drawn from the acidities found, that should be of interest to clinicians. Using methyl red (0·2 gramme in 100 c.c. alcohol) as an indicator, he says: "I cannot recall a single patient in whom it was difficult or impossible to hold the urinary acidity below that of the turning point of methyl red who did not die." At the end of the volume he gives a discussion of glaucoma considered as one of the local œdemas; he sets it down to the production or accumulation of acids or similar substances in the eye.

The book is long, and the contentious matter with which it is filled is so abundant that it is hard for a reviewer to do full justice to it in a brief compass. Dr. Fischer writes very clearly and has arranged his matter excellently. He often gives the impression that he underestimates the strength of the position of his adversaries—the believers in the importance of osmosis, for example, or of cell membranes, or of the distinction between living and dead tissues, in the metabolic processes of the living body. He has undoubtedly done good service by drawing attention to the importance of the hydration and dehydration of the colloids of the body, and the necessity for the study of colloid chemistry by those who would understand the why and wherefore of vital processes. But perusal of his pages leads to the feeling that the phrase "colloid chemistry" is but an ample cloak for our ignorance of the physico-chemical processes of living cells, and that as an explanation it takes us no further than, for example, an explanation of bacterial agglutination based on such an obscurity as Helmholtz's theory of double electric envelopes. Dr. Fischer is an enthusiast with a far-reaching theory to push, and so it is perhaps not unnatural to find his views one-sided wherever that theory is concerned. His volume makes stimulating and even provocative reading; it may be warmly recommended to all physiologists and medical men who are interested in the main subjects with which it deals—namely, œdema, nephritis, and glaucoma.

The Heart in Early Life.

By G. A. SUTHERLAND, M.D. Edin., F.R.C.P. Lond., Senior Physician to the Hampstead and North-West London Hospital; Physician to Paddington Green Children's Hospital. London: Henry Frowde and Hodder and Stoughton. 1914. Pp. 211. Price 6*s.*

THIS work deals with a subject which receives but little attention in the ordinary text-books, but which is of the greatest importance in determining a child's future course of life. The heart in childhood and youth, as in adult life, is subject both to organic disease and functional derangement, but the former is more generally understood than the latter. The differentiation between the two may be difficult, but it must be determined as far as possible. For a child's whole life may be unnecessarily hampered and its development stunted if functional disturbance is mistaken for organic mischief. There is a close similarity between the cardiac signs and symptoms of the two conditions, and the whole aspect of each case has to be carefully studied. As Dr. Sutherland points out, the period of childhood and youth has its own peculiarities and problems; there is an instability about the cardiac action which is not present in the fully developed adult heart. This instability would appear to be both in the nervous mechanism—central and peripheral—which controls the heart and in the heart itself. In early life the cardiac action is much more easily disturbed because the cardiac apparatus is not yet fully developed, hence a large number of what may be called developmental disorders and disturbances are met with.

A full description is given of the various forms of functional cardiac irregularity in the young, the cardio-respiratory form being especially considered. The diagnosis and prognosis of these irregularities are discussed at length, and this section will well repay careful study. It is rightly pointed out that if the cardiac disturbance is proved not to be of organic origin the important conclusion follows that no treatment directed to the heart is required. The patient's surroundings and mode of life must be carefully considered, and a search must be made for any source of infection or any disease in other parts of the body, particularly gastro-intestinal disorders. We agree that the majority of these disturbances are to be traced to a disordered state of the nerves, and will not be removed except by treatment directed to building up a healthy nervous system.

Organic disease of the heart in early life is also well described, and much information likely to prove of value in actual practice is given. The importance of preventive treatment is emphasised. In the case of an acute attack of rheumatic fever the possibility of carditis must always be kept in mind, and support will be given to Dr. Sutherland's contention that to prevent this complication the salicylate treatment should be thoroughly carried out, while rest during the convalescent stage should be sufficiently prolonged.

We cordially recommend this volume to those engaged in general practice who are likely to be brought into contact with a large number of the diseases—major and minor—of childhood.

Occupational Diseases of the Skin: a Brief Account of the Trade Processes and Agents which give rise to them.

By R. PROSSER WHITE, M.D. Edin., M.R.C.S., Senior Physician and Dermatologist, Royal Albert Edward Infirmary, Wigan, &c. London: H. K. Lewis. 1915. Pp. 165. Price 7*s.* 6*d.* net.

THE more widely our knowledge of the diseases of the skin extends the more do we appreciate that many of the dermatological lesions which we have to treat arise from the external influence of chemical substances and other agents with which the skin is brought into contact; and the multiplicity of modern trades has increased greatly the number of the harmful substances which are able to give rise to diseases of the skin. Up to the present no work has been specially devoted to this subject, and we therefore welcome the appearance of this book, for it will enable many practitioners to identify the causative agent of a doubtful lesion of the skin. The passing of the Employers' Liability Act has also made the matter of more importance.

While the value of the book is great in itself, it has been materially enhanced by the inclusion of a very large number of references to the original papers from which the facts included have been taken, and great credit is due to Miss A. Newbold, who has been responsible for most of these references, especially those which have been taken from foreign works and journals.

This book should have a wide circulation, as it deals with a subject which concerns all medical men who have to treat or to examine workmen.

Medical Applied Anatomy for Students and Practitioners.

By T. B. JOHNSTON, M.B., Ch.B. Edin., Lecturer on Anatomy, University College, London. With three full-page plates in colour and 146 other illustrations in the text. Edinburgh Medical Series. London: A. and C. Black. 1915. Pp. 436. Price 7*s.* 6*d.* net.

IF the question were asked what sort of book upon human anatomy could be written at the present day to fill any real gap in our already long series of text-books, an answer could easily be given: there is need for a medical applied anatomy. The ideal book is to be for the physician what so many existing surgical anatomies are for the surgeon. It is easy to name several works upon surgical anatomy, every one of which is good; but medical anatomies are few, and to recommend any treatise as a text-book which should guide the physician would be matter of considerable difficulty. To judge by the attempts that have been made, the writing of such a book is no easy matter.

It is to be doubted if even now Dr. Johnston has produced the exact book we have in mind; but it is certain he has written a very good one. The writing is clear and careful, and the accounts of anatomical conditions are for the most part excellent. The author has used judgment in assigning definite anatomical explanations for clinical phenomena, and very few criticisms could be made with any justice; it should be pointed out, however, that the commonest anatomical basis of epistaxis is as a rule very beautifully revealed to the anatomist's inspection, and that it is not a communication between nasal veins and superior longitudinal sinus *viâ* the foramen cæcum.

We think that a book so good as this should be more fittingly illustrated; the beautiful drawings of Leveillé make but poor blocks when handled by modern processes; and Sir William Turner's illustrations, which were excellent 40 years ago, could be improved upon to-day. It is doubtful if surface markings are best shown upon the cast of a classic figure, and the author's purely diagrammatic work is not always satisfying (see especially Fig. 123).

It would be a pleasure to welcome a subsequent edition of this work illustrated by a new and uniform series of anatomical drawings and diagrams.

LIBRARY TABLE.

Field Hospital and Flying Column. By VIOLETTA THURSTAN. London and New York: G. P. Putnam's Sons. 1915. Pp. 184. Price 2*s.* 6*d.* net.—The Field Hospital was in Belgium and the Flying Column in Russian Poland. Miss Thurstan was sent out by the St. John Ambulance Association in charge of a party of nurses to serve under the Belgian Red Cross. They worked at first in Brussels and in Charleroi and the neighbourhood, where they saw many examples of German "frightfulness," Charleroi being entirely burned down by means of an organised system of incendiarism. Then they returned to Brussels, whence after a little they were expelled by the Germans, being conducted as prisoners to Denmark. Miss Thurstan gives a vivid account of the hospital work in Belgium, where the detachment seems to have done admirable work under great drawbacks, but patients, doctors, and nurses worked with such a spirit that most difficulties were surmounted. The journey through Germany *viâ* Verviers, Cologne, Münster, and Kiel to the Danish frontier was made singularly unpleasant, but the party were fortunate in meeting one German officer who behaved as a gentleman and a soldier who looked after them at Hamburg. After a short stay in Copenhagen Miss Thurstan and three of her nurses volunteered for service in Russia, which service was gladly accepted. Here the Flying Column work began in Warsaw; later on the column moved to Lodz, round which there was severe fighting and terrible suffering uncomplainingly borne by the wounded. Lodz eventually had to be evacuated and 18,000 wounded were safely moved out in four days. Miss Thurstan ended her labours in the trenches at Radzivilow, where she was nearly killed by a bomb from a Taube, which exploded close to her. However, she escaped with only a slight wound in the leg. In addition to this she contracted pleurisy and was sent to Petrograd to recruit, and there this unpretending and very interesting little book was written.

Medicine (Catechism Series), Part II., second edition, pp. 180. *Operative Surgery* (Catechism Series), Part II., first edition, pp. 144. *Botany* (Catechism Series), Parts I. and II., second edition, pp. 80 and 152. Edinburgh: E. and S. Livingstone. Price 1s. each.—We reviewed *Medicine*, Part I. (second edition of this series), in THE LANCET of Feb. 7th, 1914, p. 394. Part II., now before us, deals with disorders of nutrition, chronic intoxications and sunstroke, diseases of the kidneys, and diseases of the blood and ductless glands. Like the former volume, this also appears to be well condensed and kept fairly up to date by its modestly anonymous author.—*Operative Surgery*, Part II., is another useful condensation. It deals with amputations and other operations on the extremities, and operative treatment of fractures and in the head and neck, with nerve operations, trephining, and operations on the cranium, lips, mouth, and pharynx, the neck, and the thyroid body.—*Botany*, Part I., deals with general classification, the anatomy of plants, with insectivorous plants, and with the natural orders. Part II. with the physiology and histology of plants, and includes the life-history of ferns, mosses, and an account of bacteria and fungi. For the purposes of revision and for writing up class notes such books as these serve a very useful purpose. As we have repeatedly remarked, such books are of value only when used to marshal and review knowledge already gained. If used in place of larger works they are pernicious.

Towards Racial Health: A Handbook for Parents, Teachers, and Social Workers on the Training of Boys and Girls. By NORAH H. MARCH, B.Sc., M.R.San.I. With a foreword by J. ARTHUR THOMSON, M.A., LL.D. Illustrated. London: George Routledge and Sons, Limited. 1915. Pp. 326. Price 3*s.* 6*d.* net.—The title of this very excellent little book, which no doubt Miss March has selected after due deliberation, is hardly calculated to convey an adequate idea of its scope and objects.

One of the greatest difficulties which confront parents and teachers is that of conveying to their children or pupils just that amount of knowledge in relationship to sex which is necessary for their spiritual and physical salvation. Too much knowledge, especially if given at the wrong time and in the wrong way, may do incalculable harm, whereas innocent ignorance may equally well be responsible for the most fatal results. In the very briefest, as also in the clearest, possible way Miss March explains on social, ethical, psychic, and physical grounds why this side of education should not be neglected; and not only does she explain why, but, what is far more important, she shows how instruction of this kind should be given to children and adolescents of all ages. It has been pointed out by Stanley Hall that children begin to ask troublesome questions at a very early age, between 3½ and 8 years. Miss March shows how these questions may be answered in such a way that there is nothing left to undo later. She also gives full details of a most admirable course of nature study designed to lead the child by gradual stages to a full knowledge of the significance of sex and sexual reproduction. Beginning with the fertilisation of the tulip, the poppy, and the daffodil, the child is led by almost imperceptible stages to the study of reproduction in earthworms, water snails, land snails, slugs, and other simple hermaphrodite animals. Then to the study of the same processes in the spider, the moth, and the butterfly, and finally, in vertebrate animals such as the frog, the lizard, and the chick. In a valuable appendix Miss March explains the practical details of keeping these didactic animals in appropriate incubators, aquaria, or vivaria. A difficult subject is approached in a delicate and sympathetic manner. It is hard to imagine that the most sensitive feeling can be shocked or hurt by any word expressed or idea suggested in any line of this book. It is written from start to finish in a most reverent spirit, reverent not only of the great biological principles which are unfolded throughout its pages, but also of the spiritual ties which unite parent to children and teacher to pupil. Professor Thomson has contributed a delightful preface in which he testifies to the correctness of the biological facts referred to; on the soundness from a medical and physiological standpoint of the many references to general and personal hygiene we offer Miss March our congratulations.

The Dietetic Treatment of Diabetes. By B. D. BASU, Major, I.M.S., retired. Fifth edition. Allahabad: Panini Office. 1915. Pp. 90. Price Rs1.8., or 2s. —This is a revised and enlarged edition of the little work noticed in these columns last year. The author advises the restriction, or withdrawal, of meat, alcohol, tea, coffee, and "cocoa" (i.e., cacao), and recommends milk, the leguminous meal *besan*, and "cocoanut" (by which he means "coco").

KING EDWARD VII. SANATORIUM, MIDHURST.—The Insurance Commissioners have now arranged for the removal of the non-commissioned officers and men, for whom beds have been reserved by the War Office in the King Edward VII. Sanatorium, to institutions corresponding to the localities in which the patients propose to reside. As a result the sanatorium has, from June 1st, reverted to its original purpose of receiving both male and female patients suffering from pulmonary tuberculosis who belong to the educated classes, whether in professional or kindred employments, but whose means are limited, and the sanatorium has been reconstituted for this purpose from June 1st.

THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

WEDNESDAY, JUNE 2ND.

THE Council resumed its sittings at its offices, 299, Oxford-street, W. Sir DONALD MACALISTER, the President, was in the chair.

Penal Cases.

The Council heard charges against medical practitioners.

The first case to be considered was that of Alexander Orford Schorn, registered as of Sacriston, Durham, M.B., C.M. 1892, U.Edin., who had been summoned to appear before the Council on the following charge:—"That being a registered medical practitioner you abused your position by committing adultery with a Mrs. Collins, whom you had been attending professionally, of which adultery you were found guilty by the decree of the Probate, Divorce, and Admiralty Division (Divorce) of the High Court of Justice, dated June 29th, 1914, and made absolute on Jan. 25th, 1915, in the case of Collins *v.* Collins and Schorn, in which you were the co-respondent. And that in relation thereto you have been guilty of infamous conduct in a professional respect."

There was no complainant in this case.

Dr. Schorn attended in person.

Mr. C. HARPER, the solicitor to the Council, brought to its notice the decree of the Probate, Divorce, and Admiralty Division, and certain circumstances connected with the proceedings there.

Dr. SCHORN stated, on his own behalf, that in his view he had not been fairly treated in the judicial proceedings. He denied that he had committed adultery.

The PRESIDENT said: Mr. Schorn, I have to inform you that the Council has judged you to have been guilty of infamous conduct in a professional respect, and have directed the Registrar to erase your name from the Medical Register.

The next case to be considered was that of Alfred Bertie Kramer, registered as of King's Cliffe, Wansford, Northants, M.R.C.S. Eng. 1911, L.R.C.P. Lond. 1911, who had been summoned to appear before the Council on the following charge: "That being a registered medical practitioner you have systematically canvassed for patients by visits made personally and by a Mrs. Saunt on your behalf to persons in the village of Bulwick, Northamptonshire, who were patients of Mr. Arthur Samuel Stokes. And that in relation thereto you have been guilty of infamous conduct in a professional respect."

The complainant was Mr. Arthur Samuel Stokes, M.R.C.S. Eng. 1881, L.R.C.P. Edin. 1882, of Weldon, Kettering.

Mr. Kramer attended and was represented by Mr. J. Batten, solicitor.

Mr. Stokes was represented by Mr. J. J. Parker, solicitor.

Mr. PARKER, in opening the case on behalf of the complainant, said that he wanted to allege that Mr. Kramer himself canvassed for panel patients, and he sanctioned the canvassing by Mrs. Saunt. He further alleged that Mr. Kramer obtained the medical cards of these persons, and instead of getting the people to sign it would seem that he signed them himself.

The PRESIDENT: These are insurance cards given to patients to fill in with the name of the doctors whom they chose.

Mr. PARKER: Yes. They were not filled in by the patients in this case. He had witnesses who would say that they had not so filled in their cards. The lady referred to in the course of the charge he would submit canvassed patients in Bulwick. In her declaration she said that she was not asked to do so by Mr. Kramer. Some statements were made to the effect that Mr. Stokes was not carrying on these panel patients in Bulwick. There was not a word of truth in these statements. Mr. Stokes had never said anything about it to anyone. It was pure invention. He (Mr. Parker) put in certain insurance cards which, he said, had been filled in by some persons other than the panel patients themselves. The Council would be able, he said, to examine the handwriting for themselves.

Mr. ARTHUR SAMUEL STOKES, M.R.C.S., L.R.C.P., of Weldon, then gave evidence to the effect that formerly he had 30 club patients at Bulwick, who formed the great majority of the club patients in the place. These club patients became his panel patients after the National Insurance Act came into force. Mr. Kramer started a surgery at Bulwick. He learned that his panel patients at Bulwick, all except four, had transferred to Mr. Kramer. It was not true that he had stated that he did not wish to go to these Bulwick patients. He had made inquiries as to what had been transpiring, and as a result he brought this complaint.

Several witnesses gave evidence on behalf of the complainant.

JAMES BARRATT (Bulwick) stated that Mr. Kramer had come to him and said, "I heard you were going to change doctors." He had replied that Mr. Stokes had been his doctor for many years. Then Mr. Kramer asked for his medical card and also that of his brother. He (Mr. Kramer) took the cards away with him. He afterwards found that he was transferred to Mr. Kramer's list. He had no fault to find with Mr. Stokes.

FREDERICK DOLBY (Bulwick) stated that Mrs. Saunt had asked him to join Mr. Kramer's panel. He was quite satisfied with Mr. Stokes, and he had not applied for transfer to Mr. Kramer.

Cross-examined by Mr. BATTEN, WITNESS said that he had never made any application for the medical card, but he had received it by post.

ALFRED LANE stated that in December last Mr. Kramer came to him and asked for his medical card. He said that he wanted it to be sent in, because it ought to be in next day. Witness gave him the card. He signed nothing. The medical card came to him through the post. When it came it had Mr. Kramer's signature upon it. He found that he had been transferred to Mr. Kramer. He was surprised. He wished to remain with Mr. Stokes. He was transferred back again to Mr. Stokes.

The Council sat *in camerâ* in order that it might consider a matter in connexion with the case.

The Council adjourned.

THURSDAY, JUNE 3RD.

Penal Case.

The Council resumed consideration of the case of Alfred Bertie Kramer.

The case for the complainant was continued.

Mr. FREDERICK THOMAS FISHER, M.R.C.S., L.R.C.P., was called as a witness on behalf of the complainant. He said that he had been in negotiation for the purchase of the practice at King's Cliffe belonging to Mr. Kramer. He had arranged to visit the practice on July 1st. He had had his suspicions aroused. He had heard things which he did not like, and he had made up his mind to break off the negotiations.

Mr. BATTEN (cross-examining): There was no intention of selling you the practice until after this inquiry?

Mr. FISHER: I did not know this inquiry was going on until this morning.

Mr. BATTEN: The negotiations with you were suspended. There was no attempt by Mr. Kramer to get you to complete the purchase.

Mr. FISHER: Yes. I saw his lawyer yesterday and he told me that the provisional agreement I had signed was binding and the practice was sold to me, but I refused to take it up.

Mr. BATTEN: Where did you see his lawyer?

Mr. FISHER: At Stamford.

Mr. BATTEN (addressing the President): That puts me in rather a difficulty. I should like to consider my position.

The PRESIDENT: Do you ask the Council that you should retire?

Mr. BATTEN: I would like a minute to speak to my client. I do not want to place him at a disadvantage.

The PRESIDENT: You may do so.

Mr. Batten and Mr. Kramer retired from the Council chamber.

Mr. BATTEN (returning shortly afterwards) said: Mr. Kramer appears to have fainted, and I wonder whether the Council could do any other business in the meantime and allow this matter to be suspended for a few minutes.

The PRESIDENT: Certainly.

The Council proceeded to deal with other business reported later. After certain reports had been received Mr. Batten returned.

Mr. BATTEN said that he understood from all appearance that Mr. Kramer would not be able to do anything in his case that day. He (Mr. Batten) was unable to do it for him.

The PRESIDENT: Do I understand you withdraw from his representation?

Mr. BATTEN: I do withdraw, but I feel he is not able to conduct his own defence to-day.

The PRESIDENT: You do not propose to act for him further.

Mr. BATTEN: No, sir, I do not.

The PRESIDENT said that an official of the National Insurance Commission was in attendance to inform the Council what was the normal procedure in sending in the transfers of panel patients who desired to change from the list of one medical man to that of another. He would give this information as a friend of the court and not as the witness of either party. He would ask Mr. Batten to remain in the room in the interests of his late client in order to communicate to him the decision of the Council as to any adjournment.

Mr. BATTEN assented.

Mr. JAMES RAE, an official of the National Insurance Commissioners (England), described the procedure by which panel patients could transfer by consent from one medical man to another at any time. Otherwise panel patients could only transfer at the end of the year. A panel patient who desired thus to change his medical man must give notice to the Insurance Committee before Dec. 1st. The notice could be on a half sheet of notepaper, but no notice could be accepted unless it purported to be in the name of the patient himself. With that notice had to be sent the medical card bearing the name of the old doctor.

The PRESIDENT: Does the person have a new card every year?

Mr. RAE: No. Only a new card in the case of transfer from one medical man to another. When the Insurance Committee received the notice they stamped the old card "Not available after December 31st," thus cancelling it after the end of the year. The committee prepared a new card and inserted the insured person's name and address on the outside of the card, and stamped it "Not available for treatment until January 1st." The new card was then sent to the insured person. There was no doctor's name on it when it was sent. The insured person then filled up the card and put in the name of the new doctor. The doctor if he wished to accept the insured person signed his name in the proper place. The card was returned by the doctor to the Insurance Committee so that it might put the patient's name on the doctor's list.

The PRESIDENT: What happens when a person who is insured cannot write or sign his own name?

Mr. RAE: I have seen cards where such persons have made a mark or a cross—something to identify the information as coming from them.

The PRESIDENT: Is there any practice by which bundles of these insurance cards in blank can be supplied to any person?

Mr. RAE: It is not conceivable. These cards were invariably sent direct to the insured person. The insured person should sign the card at the two places where it was indicated he should sign.

The PRESIDENT: The card filled up should contain twice the signature of the insured person and once that of the doctor.

Mr. RAE: Yes.

Mr. FISHER gave further particulars about the negotiations for the acquisition of Mr. Kramer's practice for which a sum of £750 was asked. He refused to complete the purchase.

The further hearing of the case was adjourned.

Appointment of Committees.

The following committees were appointed :—

Education Committee: Dr. Norman Moore, Sir G. Philipson, and Sir Francis Champneys (nominated by the English Branch Council); Dr. Mackay, Mr. Hodsdon, and Dr. Knox (nominated by the Scottish Branch Council); and Sir Arthur Chance, Sir William Whitla, and Dr. Little (nominated by the Irish Branch Council).

Examination Committee: Dr. Taylor, Dr. Saundby, and Dr. Caton (nominated by the English Branch Council); Sir Thomas Fraser, Dr. Russell, and Dr. Knox (nominated by the Scottish Branch Council); and Sir John Moore, Sir Charles Ball, and Dr. Kidd (nominated by the Irish Branch Council).

Public Health Committee: Dr. Newsholme, Dr. Latimer, and Mr. Verrall (nominated by the English Branch Council); Dr. Norman Walker, Dr. Cash, and Dr. McVail (nominated by the Scottish Branch Council); and Sir John Moore, Dr. Magennis, and Dr. Kidd (nominated by the Irish Branch Council).

Coördination of School Examinations in England.

A report was submitted from the Education Committee upon the recognition of certain preliminary examinations. That report stated that a communication on the subject of the examination of schools from the Board of Education had been remitted for consideration by the Education Committee of the Council. The Education Committee recommended that the Council should in reply report to the Board of Education as follows: "The General Medical Council cordially welcomes the proposed foundation by the Board of Education of a central authority to be charged with the supervision and coördination of school examinations in England, and the establishment of a system of leaving certificates. In taking this step the Council will, in fact, be reaffirming its resolutions on the subject of Nov. 26th, 1904. With reference to the recognition of the proposed examinations for the purpose of admission to the register of medical and dental students, the Council reports that the standard of the second examination, as contemplated, would appear to be satisfactory; and that that of the first, which the Council is informed is to be approximately that of the senior local examinations of the University of Oxford, would be accepted under the present regulations, provided in both instances that the several subjects required by the Council are included in the examination. These are Latin, English, mathematics, and one of the following: Greek or a modern language. This proviso would necessitate in the syllabus of the second examination, as at present planned, the inclusion of more than one 'subsidiary subject.' When the detailed arrangements have been completed the Council will be glad to receive further particulars from the Board of Education."

Dr. MACKAY moved that the Council should approve of the reply recommended to be sent to the Board of Education. He said that it would be remembered by most of the members of the Council that in 1903 and 1904 the Council had under consideration a suggestion from the Board of Education in England that steps should be taken to make uniform a large number of examinations which existed to qualify for admission to the universities and the learned professions. The Council consulted the Board of Education, which agreed in a general way to the proposals then put forward. The matter had taken a very considerable time to carry through, but the Education Committee was very glad to see that the Board of Education had at length been able to take a very definite step and to put forward agreed proposals which were now almost ripe for adoption. The Education Committee thought it highly important that the Council should again emphasise its support to the Board of Education in this most laudable step. The last paragraph of the proposed reply to the Board referred to matters which were not absolutely settled, and expressed an opinion which perhaps might lead to further discussion later.

Dr. NORMAN MOORE seconded the motion.

Sir BERTRAM WINDLE emphasised the importance of the subject. The multiplicity of examinations had previously given the Council a great deal of trouble. He only wished that there was a similar prospect of obtaining in Ireland what was now being proposed for England. If the proposal could be carried out it would be very greatly to the advantage of education generally, and to no profession would it be of more importance than to the medical. He cordially supported Dr. Mackay's motion.

The PRESIDENT remarked that it was not mentioned in the report, but it was a matter of common knowledge that the coöperation of the universities in England had been engaged in the matter, so that if it came to fruition it would be the result of the national effort on the part of all concerned. The motion before the Council amounted to this, that it should give its general support to the proposal as it did ten years ago, and ask that details should be submitted to it.

The motion was agreed to.

Pharmacists and the Medical Curriculum.

The report of the Education Committee also dealt with the question of pharmacists and the medical curriculum. That report went on to say:—"A request has been put forward by the Pharmaceutical Society of Great Britain for the recognition, for the purpose of admission to the Students Register, of the certificates attesting the preliminary examination of qualified pharmacists desirous of attaining a Licence in Medicine; and, further, for the recognition in the medical curriculum of the classes taken and the examinations in medical subjects passed by qualified pharmacists in their special course of instruction. These proposals are made in view of the present 'shortage of medical men and the possible emphasis of that shortage in the near future.' The committee would point out that the society has no preliminary examination of its own, and that among the examinations which it recognises there are many which are not accepted by the Council, on the ground that their standard is not sufficiently high. The professional course embraces botany, physics and chemistry, and materia medica and pharmacy. These subjects are studied chiefly from the point of view of their practical application to pharmacy, and the examinations appear to be amply sufficient for that purpose. The question is one which does not seem to call for any action on the part of the Council, as machinery already exists in the Students' Registration Committee under which candidates whose preliminary examination is in any respect incomplete may have *pro tanto* recognition extended to those portions which are satisfactory. So far as the recognition of the professional course is concerned, the matter is primarily one for the consideration of the licensing bodies, who have power to recognise any courses of study and examinations other than the final or qualifying examination, which in their opinion is equivalent to the course of study and examinations prescribed for the medical curriculum."

On the motion of Dr. MACKAY, seconded by Dr. NORMAN MOORE, the Council expressed its approval of the terms of the report.

Public Health Committee.

Sir JOHN MOORE intimated that no formal report would be presented by the Public Health Committee. He, however, had been requested to inform the Council that the Registrar had been asked to draw up statistics relating to passes and rejections amongst candidates for Diplomas in Public Health for the last ten years. That statistical information had been drawn up.

Indian Subordinate Medical Department.

A report was received from the Examination Committee, together with the chairman of the Education Committee and the chairman of the Students' Registration Committee, on (1) Indian Subordinate Medical Department, preliminary examinations in general knowledge and course of study; and (2) the form of the certificates to be granted to Indian graduates and students seeking admission to the Students Register of the United Kingdom. Mr. C. E. Mallett, the secretary for Indian students, wrote on March 31st that "since Nov. 11th last fresh regulations have been sanctioned by the Government of India, with the approval of the Secretary of State, for the recruitment of military assistant-surgeons of the Indian Subordinate Medical Department. The intention of the changes was to raise the preliminary educational standard for candidates for admission to the service to that required by the General Medical Council, and to extend the course of study to five years."

It was stated in the report of the Examination Committee that: "With regard to the recognition and subsequent training of members of the Indian Subordinate Medical Service applying for admission to the Students Register and seeking to proceed to licence in this country the Council in 1912 made the following recommendations to the licensing bodies: That no certificates should be accepted from the candidates except those embodied in the special forms prepared by the India Office; that a preliminary examination in general education recognised by the General Medical Council should be required; that no one of the three professional examinations of the Indian Subordinate Medical Service should be accepted; and that two years of actual study, in addition to the four years' course pursued in India, and embracing the subjects of pathology, pharmacology and therapeutics, medicine, surgery, midwifery, vaccination, hygiene, mental diseases, and anæsthetics should be required antecedent to qualification. The attestation certificate forms which were drawn up in 1912 were found by the Indian Government to be in some degree unsuitable, and were modified in 1914. The second of two communications from the India Office now under consideration intimates the approval of the new forms by the Indian Government in all respects save one, and that of a purely technical character. It had been provided originally that the attestation forms dealing with the preliminary examinations in general knowledge should be signed in all cases by a university official. The Indian Government now suggests that in the case of the preliminary examination of the United Provinces (India) Education Department the certificates should bear the signature of the secretary of the examining board. The proposal is one which solely concerns the local management, and the Council will have no hesitation in agreeing to it. In the first of the two communications the Council is informed that the course of professional study for the Indian Subordinate Medical Service will be extended in the future from four to five years, and that prior to its commencement candidates will be required to pass a preliminary examination recognised by the General Medical Council. With regard to the course of study the lengthening of the curriculum will necessitate a reconsideration on the part of the Council of the recommendations issued to the licensing bodies in 1912 dealing with the extent of the recognition to be extended to it in this country, and to this end the Council is advised by the committee to request from the India Office full particulars of the new conditions, including the subjects of study, the time devoted to each, the nature of the examinations, and the character of the teaching. In view of the intimation that the Indian authorities will in future require from the candidates a preliminary examination in general knowledge recognised by the Medical Council, the committee recommend that the 'regulations in regard to the registration of students' as published yearly by the Council be regularly transmitted to the India Office. In the present circumstances, as the older regulations were to some extent modified last year, the report of the Education Committee upon Indian examinations as adopted by the Council in June, 1914, should also be transmitted. Under the new conditions the actual 'preliminary examinations' at present conducted in India are accepted by the Council as marking the date of the commencement of the curriculum and establishing full recognition to the courses of study in chemistry, physics, and biology, but they do not of themselves entitle to admission to the Students' Register in this country, and for that end must be supplemented in each case by an additional examination specified in the list printed by the Council. The committee recommend that this report be adopted and transmitted to the India Office."

Dr. MACKAY, in moving the adoption of the committee's recommendation, said that the subject of the Subordinate Medical Service in India had been before the Council on several occasions. On the last occasion the Council took the step of saying that certificates brought by Indian students who sought recognition as students in this country should be on uniform forms which had been drawn up and approved by the Indian Government. The forms as first drawn up were not quite satisfactory, but they were altered as the report showed. The next matter with which the report dealt was of more importance. The Council would remember that with regard to subordinate medical officers, the preliminary examination was not necessarily one accepted by the Council and the course of study was a modified one extending only to four years. The Indian Government had now intimated that they proposed to change this arrangement. Under the new circumstances candidates for subordinate medical posts would be required to pass a preliminary examination accepted by the General Medical Council and also to undergo a five years' course. In these circumstances it was necessary that the Council should modify its recommendations to the licensing bodies as to the amount of recognition of the Indian course for students who came to this country. One part of the report, it would be observed, asked for details of the new five years' course. If the Council adopted the report it would get the information from the India Office in order to enable it to take effective action.

Sir JOHN MOORE seconded, and the motion was agreed to.

The Apothecaries' Hall of Ireland.

Three reports were submitted by the Examination Committee in regard to the Apothecaries' Hall of Ireland—viz., (1) report on tables furnished by the Apothecaries' Hall of Ireland in regard to examinations held in October, 1914, and February, 1915; (2) report on the tables showing the results of examinations held in June, July, and August, 1914, by the Apothecaries' Hall of Ireland, together with the reports of the assistant examiners thereon, the reply of the Apothecaries' Hall of Ireland to the committee's report, and the report of the committee on the reply; and (3) summary of particulars to be considered by the General Council in regard to a proposed representation to the Privy Council as to the licence of the Apothecaries' Hall, Dublin.

The third report contained the following conclusions: "1. Notwithstanding a considerable inducement to take the first professional examination at the Apothecaries' Hall, students do not to any appreciable extent, when commencing the study of medicine, select the Apothecaries' Hall as the means of obtaining a registrable qualification. 2. Many who obtain the L.A.H. diploma have commenced their series of professional examinations, but have failed to obtain a qualification elsewhere, and the cases given support this statement."

Dr. MAGENNIS observed in relation to the third report that it was hardly fair to expect him to reply completely to it as he had not received previous information of its contents. A copy of it might surely have been given to him the night before. In these circumstances it was only fair that its consideration should be postponed until the November session.

Sir CHARLES BALL moved: "That it appears to the General Council that the course of study and examinations to be gone through in order to obtain the qualification of Licentiate of the Apothecaries' Hall of Ireland are not such as to secure the possession by persons obtaining that qualification of the requisite knowledge and skill for the efficient practice of their profession." He said that as long ago as 1895 a somewhat similar question arose before the Council. From 1888 to 1894 a Conjoint Board had existed between the Royal College of Surgeons in Ireland and the Apothecaries' Hall for the purpose of holding qualifying examinations in medicine, surgery, and midwifery. It was frequently inspected, and it was reported that the medical portion of the examination was not sufficient. This was reported in the ordinary way to the Privy Council. Before the Privy Council had heard the case the Royal College of Surgeons withdrew from the conjunction, and the Privy Council replied that it appeared to be unnecessary for it to come to a decision as the Conjoint Board was no longer in existence. There had been no inspection of the Apothecaries' Hall of Ireland under the Medical Act, 1886, since 1902, but instead of that assistant examiners were required to report to the General Medical Council on the whole final examination, not only in surgery, but in medicine and midwifery. From this time on the assistant examiners furnished reports. Some of these contained very useful information. They almost invariably reported that the final examinations were sufficient. In May, 1913, it was decided to discontinue the reports from assistant examiners on the subjects of medicine and midwifery at the final examinations of the Apothecaries' Hall, and to appoint a representative or deputy to be present at all the examinations other than surgery held by the Hall, and to report thereon. Dr. J. Magee Finny was appointed. In 1895 the Apothecaries' Hall said before the Privy Council that one of the reasons why their power to grant qualifications should not be withdrawn was that "young men who cannot afford to pay high fees for examination elsewhere pass the examination at the Hall at moderate cost." The fact was that the fee charged by the Apothecaries' Hall for the first professional examination was only one-third of that charged by the Conjoint Board of the Royal Colleges in Ireland for the same examination, but the total fees charged for the subsequent examinations, including the final examination, were the same for both bodies. As would be seen from the summary of particulars, Dr. Finny had reported that during the year when he acted as deputy, in which there were four stated examinations, no candidate presented himself in all the subjects of the primary professional examination, while only a single candidate presented himself at one examination in physics and biology, and he withdrew before the oral portion of the examination. The Apothecaries' Hall said that the reason they had so few students for the early examinations was that the General Council refused to register as medical students candidates who had passed the preliminary arts examination held by the Apothecaries' Hall. By direction of the Council (Sir Charles Ball, still quoting from the summary of particulars, proceeded to say) the Examination Committee made an analysis of the returns sent in by the various licensing bodies as to the exemptions granted from professional examinations. This analysis was made for the five years 1907 to 1911. The returns furnished by the Apothecaries' Hall showed that during that period 51 candidates were granted exemption from some portion of their professional examinations on the ground that they had passed similar examinations elsewhere. During the same period only 37 candidates passed for the L.A.H. diploma, and the returns furnished to the Council did not show whether any one of the 37 candidates had passed all the professional examinations at the Apothecaries' Hall. These facts showed that students did not to any appreciable extent select the Apothecaries' Hall from the commencement of their professional course as the means whereby they might obtain a registrable qualification in medicine, surgery, and midwifery. The committee believed on very strong evidence that almost all the candidates who came up for these examinations were those who, having passed some of their professional examinations elsewhere, had failed to obtain their qualification elsewhere. It seldom happened that the full previous professional history of candidates who took the L.A.H. came under the notice of the Council, but statements were obtained by the Registrar from the licensing authorities concerned relating to three gentlemen who registered on the L.A.H. between May, 1912, and March, 1913. He would like to draw the attention of the Council to what the summary of particulars said. This was the passage:—"Mr. X., registered as medical student Dec. 26th, 1911, was rejected in all three subjects of the First Professional Examination held by the Scottish Conjoint Board January, 1912, was rejected in chemistry and biology, but passed in physics March, 1912. He registered the diploma L.A.H. Nov. 25th, 1912, less than one year from the date of registration as a medical student. Mr. Y. was rejected twice in chemistry and once in biology at the First Professional Examination of the Irish Conjoint Board. He was afterwards rejected twice in anatomy and once in physiology. In January, 1912, he was examined for the fourth time in pathology and obtained no marks. He subsequently obtained the L.A.H. at a time when the separate examination in pathology had been temporarily discontinued. He registered in March, 1913. Mr. Z. had been rejected six times in pathology, three times in materia medica, seven times in forensic medicine, and four times in medicine, the only portion of the Final Examination at the Irish Conjoint Board at which he presented himself. On the last occasion (January, 1910) he obtained 70 out of a possible 250 in clinical medicine. He registered as L.A.H. in May, 1912. The Apothecaries' Hall have declined to discuss these cases, but have not challenged the facts." The reason why the Apothecaries' Hall of Ireland declined to discuss these cases was because the gentlemen in question had become qualified. It was true that Dr. Finny, who attended from 1913 to 1914, spoke favourably of some portions of the examinations, although he made serious comments on other portions. It was desirable to recall to members of the Council some of the things that Dr. Finny said. For instance, in regard to physiology at the examination in July, 1913, he reported: "The very smallest acquaintance with the subject seemed to satisfy the examiner, and the questions were by no means of a searching character." He further reported: "The facilities for an examination in practical physiology were *nil* with the exception of the microscope in histology." In pathology he said that in July, 1913, the only examination was in connexion with the orals in medicine and surgery. In 1914 the separate examination was reinstituted. Dr. Finny spoke favourably of this new examination, "now that it is given a special place to itself in 1914; previous to this change it was open to grave objection." The motion which he (Sir Charles Ball) now proposed was a simple one. What would happen if it was adopted by the Council? It became a question for its further consideration whether any move in the direction of reporting to the Privy Council should be carried out. But the passing of the motion did not in any way bind the Council to report its finding to the Privy Council. The Medical Act said that "if it appears to the Council ...... it shall be lawful" for it to represent to the Privy Council. It was not incumbent on the Medical Council to make the representations. The Council might do so if it desired. There were one or two points which he desired to mention. A gentleman who registered as a member of the Apothecaries' Hall of Ireland had practically all the advantages of any other registered medical practitioner. A large proportion of those who took this particular diploma very soon afterwards came to some of the Royal Colleges, and presented themselves as registered medical practitioners seeking the separate licences given by those Royal Colleges. If the gentleman succeeded in passing the examination he could come and register his new qualification, not as an additional one, but in substitution for his first acquired one.

Mr. VERRALL seconded the motion. In November he seconded the proposal for an inquiry, and now, having satisfied himself of the justice of this motion, he proposed to second it. Sir Charles Ball spoke out of full knowledge on this matter. He did not think that, subject to any explanation or reply, anybody could doubt that there was a substantial case for impugning the value of these examinations. Even if the Council were prepared to continue the expense of supervising this particular examination there was no proof that it would provide such a test of candidates as the Council was bound to see was given.

Dr. MACDONALD moved as an amendment, "That the further consideration of the motion be adjourned to the November session." He said that his reason was that the report had not been long enough in the hands of the Council for consideration. The report only came into the hands of members that day. It might be necessary to pass the motion, but they should first have time for consideration.

Sir HENRY MORRIS seconded the amendment. He said that he was at a loss to know what would follow if this motion was passed. If it were passed there would be no alternative, if the Council acted consistently, but to send it to the Privy Council. If the Council did not think that course should be taken, then he wanted to know what course would be taken. Surely the Council would not pass a resolution of this sort without something following on it. It was clear that if the Council passed a resolution of this sort something ought to be done to take care that if the examinations were to be continued the course of study should be such as to bring the examination up to a proper standard. He confessed that he did not see the point of Sir Charles Ball's remarks about the man who had got the L.A.H. coming to London and getting the M.R.C.S. and the L.R.C.P., and substituting that qualification for the L.A.H. on the Register. Why should he not? He was sure that Sir Charles Ball did not mean to insinuate that the Royal College of Surgeons of England was likely to pass a man any easier because he was a possessor of the L.A.H. It was quite possible that the man might pass the examination because of the amount of study which he had done after obtaining the L.A.H. He was sure Sir Charles Ball could not have made the remark to prejudice the body for which he (Sir Henry Morris) was speaking. It was unhappy that he should have made the remark.

The PRESIDENT said that he would explain what courses were open if the motion was passed. Some time ago legal opinion was taken on the consequences of motions of this kind. He was advised that the Act was clear. The Council was entitled to pass such a resolution as this, but it was not obliged by anything in the Act or in the nature of the case to report it to the Privy Council. The alternative course was to send the motion to the Apothecaries' Hall of Ireland along with the summary statement on which the motion was based, and to invite any reply or any suggestion of improvement or any suggestion of alteration of the present system which the authorities of the Hall might desire to bring to the notice of the Council. That could be done if this motion was passed and the Council saw fit.

Sir JOHN MOORE said that he would vote against the amendment. It was futile to say that this subject was sprung on the Council. It was all very well for people in England to talk about it. But as representative of the

Royal College of Physicians of Ireland he could say that one candidate who was rejected at its final examination went over to the Apothecaries' Hall of Ireland and passed for the L.A.H. He afterwards came back and asked the Royal College of Physicians to examine him again. He was rejected. The Royal College had thought it necessary to alter its by-laws, and to say that it would not accept any medical practitioner unless he fulfilled certain conditions. The thing was becoming little short of a scandal. This matter should not be postponed unduly. It had been dragging on year after year, and was damaging the standing of medical men in Ireland.

Dr. Norman Moore did not regard the motion as necessarily hostile to the Apothecaries' Hall of Ireland. It was not deliberately intended to injure that body, and he would vote for it in the hope that it would do good to the Hall and lead to its reformation. It was quite clear from the discussions which had taken place in the Council that it needed reformation. At the same time it would be very wrong to send this resolution to the Privy Council. That would be a hasty act, which the Medical Council should not do. This was a final opportunity to the Apothecaries' Hall of Ireland to put its house in order. The question of the Hall's examinations had been before the Council for ten years.

Dr. Little observed that the matter had been under consideration not 10 years, but 30 years.

Dr. Magennis said that the motion was practically a first attempt at the extinction of an old Irish institution. On the reports of Dr. Finny he thought that any court would come to the conclusion that the examinations of the Hall were sufficient. The reports which had been submitted to the Council would show that they had been improving year by year. He maintained that the examinations in medicine and surgery were as difficult as those held elsewhere. His great difficulty as representative of the Apothecaries' Hall of Ireland in dealing with this report was that he had received it only a very short time ago. To him Sir Charles Ball had appeared to be the prosecutor in this case.

Sir Arthur Chance expressed sympathy with Dr. Magennis in regard to the short notice he had had.

Dr. Caton said that it was with great reluctance that many members of the Council had been forced to the conviction that the examinations in question were not satisfactory. This opinion was the cumulative effect of a very large number of points that had been brought forward not only now but in the past. They felt that there was a need either for reform or for extinction. He was, however, strongly opposed to the motion being sent to the Privy Council. It should be sent to the body immediately concerned so that it might have an opportunity of considering it and making the necessary reforms. If no reforms were made then the Council ought to send this or a similar motion to the Privy Council.

Dr. Saundby hoped that the motion would not be postponed, but that it should be passed and sent to the Apothecaries' Hall of Ireland.

The amendment of Dr. Macdonald was rejected on a show of hands.

The motion of Sir Charles Ball was carried by 29 votes to 2. Three members did not vote and four were absent.

Dr. Norman Moore moved that "this resolution, together with the report of the Examination Committee on the summary of particulars, be forwarded to the Apothecaries' Hall of Ireland for its information."

Sir Henry Morris seconded. He thought that it was reasonable that some indication should be given to the Apothecaries' Hall in what way modifications or additions to their curriculum and examinations should be made.

Dr. Magennis said that it would be unfortunate if the authorities of the Apothecaries' Hall, who were anxious to improve and who had improved their examinations, were not assisted by the Council as to the manner in which they ought to improve them. Any recommendations or suggestions made by the Council to the Apothecaries' Hall, he would guarantee, would be stringently carried out.

The President remarked that the Council could not undertake the duty of governing a body which was capable of governing itself. The Council could not both pass the final verdict on these matters and at the same time be responsible for the regulations.

The motion was agreed to

The Pharmacopœia Committee.

The President submitted the report of the Pharmacopœia Committee, which was in the following terms: "Up to the end of the year 1914 the total sales of the British Pharmacopœia (1898) amounted to 46,535 copies, and those of the Indian and Colonial Addendum amounted to 4529 copies. The British Pharmacopœia (1914) was issued in pursuance of the Council's instructions on Dec. 31st, 1914. Up to May 29th, 1915, the number of copies sold amounted to 17,239. As the first issue of 20,000 copies is thus nearly exhausted, a second issue of 10,000 copies has been prepared and will shortly be ready for distribution. The opportunity has been taken to amend the typographical faults which were noted in a slip attached to the first issue, together with a few others of minor importance. The only alteration in the text which calls for notice is that referring to the specific gravity of guaiacol. This should read 1·116 to 1·140. The Government of India has intimated that no special edition of the Pharmacopœia for use in that country will on this occasion be required. The Belgian Government has courteously undertaken to inform foreign governments, who were parties to the international agreement of 1906, of the publication of the British Pharmacopœia (1914) and of the manner in which effect has been given therein to the recommendations the agreement contained. The Finance Committee have furnished figures relating to the expenditure of the Pharmacopœia of 1914, as compared with that on the Pharmacopœia of 1898, which show that a saving of about £2205 has been effected in the case of the former. A large proportion of the saving is due to the advantageous arrangements made with the printers and publishers, and to economy in the expenses of the committee. The committee have received with regret the resignation of their secretary, Dr. Nestor Tirard. He has held the office for 20 years, and during that time has seen through the press the Pharmacopœia of 1898, and has acted as senior editor of the Pharmacopœia of 1914. His services to the committee have been many and valuable, and have been rendered in a manner which won for him its constant esteem. His important duties as commanding officer of the 4th London General Hospital occupy his time so fully that he is now constrained to limit his other engagements. The committee, in accepting Dr. Tirard's resignation, conveyed to him an expression of their high appreciation. They suggest that the President should be authorised to express to him, in the name of the General Council also, its grateful acknowledgments of his able work on its behalf."

The President, in submitting the report, drew special attention to the passage in which the committee expressed its regret at the resignation of Dr. Tirard and its high appreciation of his work. He was sure that the Council would desire to authorise him to convey to Dr. Tirard the expression of their appreciation of his long services.

Members: Hear, hear.

The President said that the members of the Council all recognised Dr. Tirard's devotion to the country, which had induced him to lay down his office as secretary of the Pharmacopœia Committee in order that he might fully devote himself to his military duties.

It was then agreed by the Council that the President should be authorised to convey to Dr. Tirard "its sense of the very valuable services which he had rendered in the course of the last 20 years as secretary of the Pharmacopœia Committee and editor of the British Pharmacopœia, 1914."

Students' Registration Committee.

A report was submitted from the Students' Registration Committee.

On the motion of Dr. Norman Moore it was resolved (1) "That satisfactory evidence as to visitation having been received, Reading School, Blaenau Festiniog County School, and the Intermediate County School, Towyn (Merionethshire), be added to the list of recognised teaching institutions approved by the Council"; and (2) "That the City of Dublin Technical Schools be added to the list of recognised institutions approved by the Council, so far only as their day classes are concerned."

Appointment of Registrar.

On the motion of Dr. Norman Moore, seconded by Sir Henry Morris, Major Norman C. King was reappointed Registrar for the ensuing year.

The Council adjourned.

FRIDAY, JUNE 4TH.

Penal Case.

The Council resumed the consideration of the case of Mr. A. B. Kramer.

The PRESIDENT said: I have received a telegram from Mr. Kramer: "Sorry unable to appear. Letter following by express messenger." The letter has just come. It says: "I wish to apologise for the inconvenience and delay caused by indisposition yesterday, and after a bad night I feel quite unable to appear at the Council this morning as wired a short time ago. If the Council will be good enough to postpone the hearing until I am well enough to appear all the accusations brought against me will be fully answered." A telegram and a special messenger have been sent to Mr. Kramer stating that the case is proceeding and his presence is desired. No medical certificate has been sent indicating that he is unable to be present. I have asked the Insurance Commissioners to allow one of the local officials, Mr. Groves, to come as a friend of the Council and give us such information as is in his power, not as a witness upon either side.

Mr. GROVES, clerk to the County Insurance Committee of Northamptonshire, said that intimations of the time at which transfers of panel patients could be made were inserted in the local newspapers. It was therein stated that the notices must be in before Dec. 1st. He described the procedure adopted in the transfer.

The PRESIDENT: Do you issue a blank card to a person who has not applied for a transfer?

Mr. GROVES: Certainly not.

Were there many applications for transfer in the district of your committee last November?—Approximately 240 in the whole of the county.

Can you say whether there were many applications for transfers in Bulwick?—I can tell you how many Mr. Kramer had transferred to him. There were 91 cases in which people transferred from another doctor to him.

Of the 91, had all been preceded by an application on behalf of the insured person for the transfer?—Yes.

Do you take any steps to ascertain the authenticity of a notice to transfer?—No. We accept the letter. We verify that there is an insured person. We do not verify the handwriting or the signature.

Mr. GROVES handed in the original applications for transfer in a number of cases.

The PRESIDENT: Will you look at these cards? (Certain cards were handed to Mr. Groves.) Will you look how the body is filled up? Is that in the same writing as this application?

Mr. GROVES: I should think so. In his experience the insured person frequently only signed the card at one place.

Mr. PARKER addressed the Council.

The PRESIDENT stated that the messenger who had been sent to Mr. Kramer reported that he had left his lodgings and it was not known where he had gone.

After deliberating *in camerâ*, the PRESIDENT said: "I have to announce in public that the Council have adjudged Alfred Bertie Kramer to have been guilty of infamous conduct in a professional respect, and have directed the Registrar to erase from the Medical Register the name of Alfred Bertie Kramer."

Dental Education and Examination Committee.

Mr. TOMES submitted the report of the Dental Education and Examination Committee. He said that an application had been received from the National University of Ireland that their degrees of Bachelor of Dental Surgery and of Master of Dental Surgery should be recognised, particulars of the curriculum prescribed by the University being submitted. In accordance with the recommendation of the committee he moved: "That the degrees of Bachelor and Master of Dental Surgery of the National University of Ireland be recognised."

Dr. KNOX seconded.

The motion was agreed to.

Mr. TOMES said that an application had been received from the University of Melbourne that their degree of Bachelor of Dental Surgery be recognised. This degree was only obtainable by those who had gone through the courses for the Licence of Dental Surgery, and this licence was granted to them. The licence was already recognised by the Council, so that the question was merely the admission of the Bachelor degree to the columns of the Dentists' Register. He concluded by moving that "the application of the University of Melbourne should be acceded to."

Dr. KNOX seconded.

The motion was agreed to.

Mr. TOMES went on to refer to a passage in the report which stated that "an application has been received from the University of Illinois (i.) that its College of Dentistry be recognised as a teaching body; (ii.) that its degree of Doctor of Dental Surgery be recognised. With regard to (i.) it is pointed out that the recognition of schools as teaching bodies does not lie in the hands of the General Medical Council; with regard to (ii.) the curriculum extends to only three years instead of four as in Great Britain. The information furnished as to the scope and conduct of the examinations is quite insufficient to enable the committee to judge of them." He moved that "the application of the University of Illinois be not acceded to."

Dr. KNOX seconded.

The motion was agreed to.

The Alleged Deficiency of Qualified Dentists.

In its report the Dental Education and Examination Committee narrated the steps which had been taken in pursuance of a resolution of the previous session under which the committee was asked to consider and report on questions affecting the dental curriculum and the supply of dental practitioners. Power was given to the committee to communicate with the licensing authorities on the subject. The report stated that a letter had been sent to the licensing authorities on March 11th by the acting registrar. It was in the following terms:—

"At the November Session (1914) of the General Medica Council Dr. Newsholme, medical officer of the Local Government Board, called attention to the fact that the number of dental practitioners registered in the Dentists' Register showed no appreciable increase since the institution of the Register 36 years ago. The total number on the Dentists' Register for 1879, which included all those in practice prior to the passing of the Act in 1878, was 5289, of whom 9·17 per cent. possessed dental qualifications granted by the licensing bodies; the total number in the Register for 1915 is 5426. A steadily growing proportion, now amounting to 71·08 per cent., are registered in virtue of qualifications granted by the licensing bodies, but the additions from this source are not more than sufficient to make up the loss by death or removals. It was suggested that the supply of registered dentists is insufficient to meet the increasing needs of the population; and it was pointed out that in recent years dental practice by unqualified persons had undergone a very great extension in many parts of the country. The General Medical Council expressed no opinion on the statements made in the course of a short discussion, but instructed its Dental Education and Examination Committee to consider them, to make on behalf of the Council such inquiries as might be of service, and to report to the Council at its session in May, 1915. Amongst the questions suggested for consideration by the Committee are the following:—Assuming for the moment that there is a real shortage of qualified dentists, and that it is desirable in the public interest that their numbers should be increased to a considerable extent: (1) To what extent is the deficient supply attributable to the failure of the existing law, as judicially interpreted, to check unqualified practice? (2) To what extent is it due to the inability of candidates to pass the required preliminary examination in Arts before commencing professional study. (3) To what extent is it due to the length, stringency, and expensiveness of the courses of professional study and examination required for qualification? If the points enumerated in the latter (3) be thought to be important factors: (4) What modifications, if any, are possible in the direction of lightening the present curriculum without impairing the sufficiency of the guarantees for efficient practice contemplated by the Dentists Act? As one of the authorities interested you are invited to communicate to the Council's committee any conclusions your experience may have enabled you to form on these points, and upon the subject of dental education and qualifications in general. Such communications will, if it is so desired, be treated by the committee as confidential, in so far as that their source will not be disclosed without the authorisation of the body concerned."

The report went on to state that a covering letter was sent by the chairman of the committee to each of the dental schools, in which the further inquiry was made whether the supply of students was or would be affected by the ultimate selection of one or other of the alternative methods of obtaining instruction in mechanical dentistry—viz., at the hands of a private practitioner or in a department of a dental school. The committee regretted that as it had up to the present received answers from only about half the number of the licensing bodies and from a somewhat larger proportion of the teaching bodies, it was not in a position to make a complete report nor to make any recommendation. It was within their knowledge that some of the licensing bodies who had not yet answered had the matter under careful consideration, but were not yet in a position to make their report.

Dr. SAUNDBY mentioned that the body which he represented was considering the matter.

Sir HENRY MORRIS said that his College was also considering it. A joint committee was considering the matter to see whether any change could be made which might be advantageous to the public and the profession.

The report was adopted.

National Insurance Act Committee.

On the motion of Dr. KIDD, Sir Arthur Chance was appointed an additional member of the National Insurance Act Committee.

End of the Session.

At the close of the session of the Council on Friday, June 4th, it was intimated that Major N. C. King, the Registrar, who was present in khaki, had been instructed to report himself for duty with the 3rd Battalion of the London Rifle Brigade at Tadworth Camp. Major King received the good wishes of the Council on his departure. It is understood that he will be called to an important command in his regiment.

On the motion of Dr. NORMAN MOORE, a vote of thanks was passed to the President for his services in the chair.

The session then came to a conclusion, and the Council rose to meet again in November.

THE VALUE OF ANTITYPHOID INOCULATION.

IN view of the opposition that continues to be made in some quarters to the use of antityphoid vaccination, we are enabled, through the courtesy of Dr. L. S. Mackid, to publish the following report made by him as medical officer at Calgary, Alberta, Canada, to the Canadian Pacific Railway, on the results of a systematic antityphoid vaccination of the company's employees extending over the three years 1911–13:—

With the large increase of the population in the western country during the last few years it has been a hard matter to keep pace in a sanitary way with the growth. This is true not only of this country, but of all new districts which open up, and as a result we suffer from those diseases which follow insanitary conditions. Our worst enemy in this field is typhoid fever. To a large company like the Canadian Pacific Railway the presence of typhoid means a very great loss, much more than one would imagine without going into it thoroughly. We have already done our utmost to fight the condition by sanitation, and have been greatly rewarded for our efforts. We followed pretty closely the rules as laid down by the military authorities covering the sanitation of the camps. With the introduction of typhoid vaccine into the armies of the world and the marvellous results that have been recorded we decided to introduce it into the railway world.

To give an idea what typhoid means to a big company a few figures are given. When a man goes down with typhoid he is incapacitated for a period of at least four months, or in terms of days about 120 days. In the year 1911 there were about 320 cases of typhoid fever on the Alberta Division, which means a loss of time to the company of 38,400 days. Again, this disease comes just at the time of the year when these men are most needed, that is, in the fall of the year, when the work is being finished before the oncoming winter, and when the company is getting the harvest away and placing coal and other winter supplies all over the country. Now if it means all this to the company what does it mean to the man himself? It means that he is incapacitated just at the time when there is plenty of work for him to do. It means a heavy raid on his financial condition for medical, hospital, and convalescent expenses at the time of the year when he can least afford it.

Initial Difficulties.—Technique and Reactions.

Having all this in our minds we decided to approach the company and get their coöperation, and were met more than half-way in the scheme. This, however, was only the starting point, as we still had to get the consent of the men, as it was upon them that the vaccine had to be used. We interviewed as many as possible and placed the proposition before them as clearly as we could and were more than satisfied to find that a great number entered in the work, sufficient, at least, to warrant our going ahead with the vaccination. All the district surgeons were also eager to start ahead with the work as soon as possible. We soon found out that our troubles were only commencing. The men all had very painful recollections of having been vaccinated for small-pox and immediately put typhoid vaccination in the same category. We were also dealing with a non-disciplined lot of men whom we could not force to be vaccinated, so it had to be optional, and in several places it required a great deal of patience and some hard talking to convince them that it was being done for their own good.

For the complete treatment we used three inoculations at intervals of 10 days. The first inoculation consisted of 8 minims containing 500,000,000 killed bacteria. Ten days later a second inoculation of 15 minims containing 1,000,000,000 bacteria, and again, 10 days later, 15 minims of 1,000,000,000 bacteria. The site of the inoculation was chiefly the upper arm, either at the insertion of the deltoid muscle or the back of the arm into the triceps. These injections were done as far as possible in the afternoon, so that the reaction would be all over by morning. A few hours after the injection the reaction commenced like an oncoming attack of "la grippe"—slight headache, general soreness, lassitude, slight elevation of temperature, and in some cases slight nausea. This lasted for about 10 hours and was then completely gone. The local reaction was redness, pain, swelling, and heat. This lasted longer than the general symptoms, but was pretty well over in 48 hours. We used the ordinary hypodermic syringe with several needles, which were sterilised by boiling, a separate needle being used for each inoculation. The site of inoculation was simply prepared by painting with iodine, and after the injection was done no dressing was applied. Some of those inoculated showed more severe symptoms than the rest, such as syncope, which lasted for a short while, and was recovered from without any treatment. Examination of these men showed no reason why it should have happened. We found no condition that we could classify as a contra-indication to vaccination. As to the time lost as the result of the vaccination, about 95 per cent. of the men kept right on at their work. The other 5 per cent. were laid off for not longer than 48 hours.

Results Showing the Value of Antityphoid Vaccination.

In 1912 there were about 5500 inoculations done with two cases of typhoid developing amongst them, and one of these two had only received one injection and came down with the fever a few days later, so that it is possible that he was coming down at the time of the inoculation. Among the other men living under exactly the same conditions as the men who were vaccinated there were 220 cases of typhoid.

One of the most striking results of the vaccine was in a gang of about 35 men, who were camped within the city limits, and who absolutely refused to be vaccinated at first. In this camp 11 cases developed, and then the men began to ask to be vaccinated, which was done, and following it we had the only other case.

Dr. Maclaren, Dr. King, and Dr. Green used the vaccine in the treatment of cases, using at each injection small doses, the first of 1,000,000 bacteria and doubling it every fourth or fifth day. They found that in those cases which were treated from the beginning of the disease the complications were almost *nil*, although it did not lessen the course of the disease at all. Those cases that were well advanced before they came in under treatment showed no effect at all, the vaccine here being more harmful than beneficial.

For 1913 we have not as yet received all the reports, so can only give an incomplete report. So far the total number vaccinated is 2771, with 1 case developing fever, and against this there are reported 70 cases amongst the non-vaccinated. When all the reports are in, these figures will probably be between 8000 and 10,000.

The conclusions that we draw from this work are :—

1. We have a very valuable aid for the prevention of typhoid fever in the use of vaccine.
2. The name of vaccination should be abolished and inoculation should be used in its place.
3. When cases of typhoid come under observation early enough most of the complications can be lessened.
4. The use of the method should be advocated in all places where men are to be in camp and under doubtful sanitary conditions for any period of time.
5. The period of immunity is apparently indefinite, probably equal to that produced by a single attack of typhoid.

Since this report was made the various lists to complete the work for 1913 have been sent to us by Dr. Mackid. The additional number vaccinated was 8400 with only the one case developing, making a total vaccinated of 13,900, among whom 3 cases of typhoid developed. The figures read as follows ;—

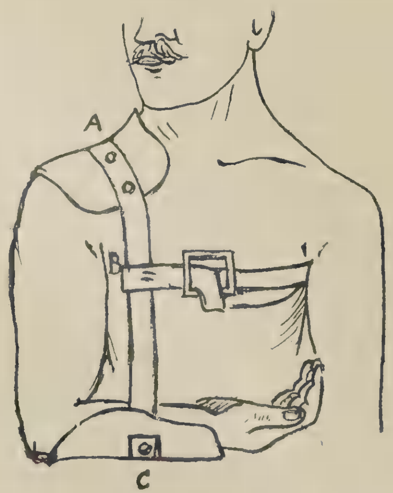
Total number men employed	24,000
,, ,, vaccinated	13,900
Number of cases among non-vaccinated ...	290
,, ,, ,, vaccinated	3

New Inventions.

A USEFUL SHOULDER-SPLINT.

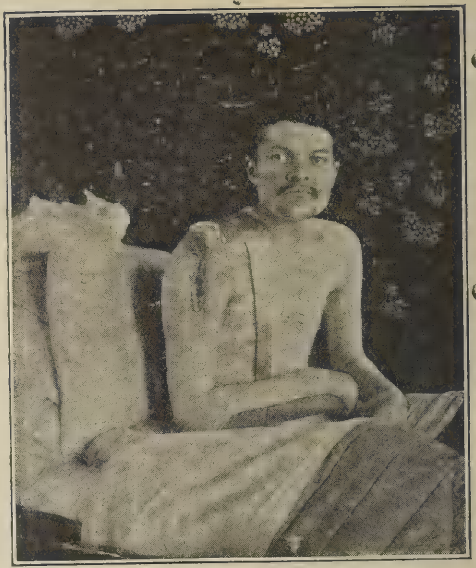
AFTER excision of the shoulder-joint it is often difficult to give the necessary support to the arm, and a splint which acts perfectly in the sitting position may be quite unsuitable when the patient is lying down.

FIG. 1.



The one here described is very comfortable and easily made, as well as cheap. It is S-shaped in side view, fitting *over* the shoulder and *under* the forearm. It consists of a kidney-shaped shoulder-piece (Fig. 1) A, of thin zinc or sheet steel, 7 × 3½ inches, or wide enough just to clear the neck muscles and the acromion on either side. This is riveted to the upper end of a piece of galvanised iron strap 1¼ inches wide and 1/16 inch thick, so that it (the latter) can be bent on its long axis to fit the chest. The splint C for the forearm is approximately 10 inches long and of the ordinary trough pattern, or long enough to reach to the wrist. It will be found that the forearm varies very greatly even in persons of the same height. This part of the splint is riveted to the upturned end of the upright strap-shaped bar at C. The whole splint is kept in place by a strap and buckle passed from a slit in the shoulder-piece behind and under the opposite axilla. The splint must, of course, be moulded and bent to a perfectly snug fit, and as a refinement a still more perfect result can be obtained by inserting a piece of house flannel soaked in plaster-of-Paris under the shoulder-piece, padded with wool, when the splint can be bent to fit this at leisure. The arm is bandaged to the side at night and the wound can be dressed without removing the splint.

FIG. 2.



The cost of the above is trifling and, what is more, the materials can be got even in an out-of-way French town, and it can be put together by anyone of the slightest mechanical ability.

J. CROPPER, M.D. Cantab.

Anglo-Ethiopian Hospital, France.

A RUSSIAN WOMAN DOCTOR.—According to the *Novoe Vremya* M. G. Stanishevskaya has been appointed *privat-docent* of the chair of pathology in the Imperial Novorossisk University. She is the first woman to receive this appointment in a Russian university. She finished her medical studies in Nancy in 1899, passed her examinations in the Moscow University in 1900, and in 1913 presented and defended a treatise for the degree of M.D.

BIRMINGHAM HOSPITAL FOR NERVOUS DISEASES.—The second annual report of the Birmingham and Midland Hospital for Nervous Diseases states that the new cases treated were 1093 and the total attendances numbered 13,215. Among the conditions most frequently dealt with were epilepsy 122 cases, neurasthenia 176, acute neuralgia 48, hysteria 34, neuritis 23, alcoholism 20, dementia and insomnia 18 each, and melancholia 16. The experience of the last two years has emphasised the need for beds. There has been a great increase in the employment of massage, and electrotherapy has been used with considerable success, so that the expenditure of £300 for the installation of more up-to-date electrical appliances has been sanctioned. The year's income amounted to £892, which left a favourable balance after payment of expenses of £143.

THE LANCET.

LONDON: SATURDAY, JUNE 12, 1915.

The Metropolitan Hospital Sunday Fund.

THE public is truly generous in its contributions to charity, and on the whole our general benevolence takes a practical rather than a sentimental form. Before the purse is opened the prospective giver seeks for proof that the exercise of his charity is needed. The professional beggar and the secretary of the faked charity both know this well, and will provide with fluent pen all the documentary evidence that the most exigent can desire, but while the harvest of the charlatans is great—far too great—the written word never speaks with the same force as the revealed fact. A mining disaster, a shipwreck, or a factory explosion appeals to the reason as well as to the imagination, and the realisation of the need at once calls forth a hearty response both in money and in personal help when the latter is required. It is the visible proof of their work that enables the hospitals of the metropolis to secure the amount of voluntary support that they receive, and in the same way it is the unrevealed character of much hospital energy which prevents that support from being as large as it should be. For there is little or nothing to stir the imagination of the public and help them to comprehend the enormous amount of sickness and suffering that is being ministered to daily within the walls of our great hospitals. In one large London hospital alone over 16,000 in-patients, nearly 170,000 out-patients, and 3917 maternity cases are treated yearly, and the Metropolitan Hospital Sunday Fund, in common with the King's Hospital Fund for London, exists to help 126 hospitals, to say nothing of other institutions. This year the privacy which surrounds hospital work has been modified by circumstances; the case of the sick and wounded soldiers has been public property and there is a wider knowledge of what hospitals really can do. The figures of admission to the London hospitals will be multiplied owing to the war, and will in themselves make a more powerful appeal than usual on behalf of the sick and suffering, but figures do not convey to the mind the vivid picture which the interior of our hospitals presents to the eye. It would not be practicable or decent to admit into the wards of our hospitals everyone who had a desire to see for himself the work of healing which is there carried on, but the hospital treatment of our wounded soldiers and sailors has been so ably described by the public press that there will be no excuse for not realising at any rate one side of hospital activities The skill and experience of the medical, surgical, and nursing staffs of our voluntary hospitals, and the completeness of equipment of these institutions, naturally make them the best possible places for treating such of the wounded as can be moved from the seat of war, and the hospitals have responded most generously to the call which the country has made upon them. This has not been done without entailing an expenditure severely taxing their already overburdened resources, and in many cases the burden has been increased by the necessity for extending existing accommodation and the difficulty of maintaining an adequate personnel.

If the public could fully realise the enormous amount of good work that is being done by our hospitals, not only on behalf of the poor, but indirectly also in the interests of those who are able to pay for medical treatment, there would, we feel sure, be a larger response to the yearly appeal which is made on behalf of the London hospitals by the Metropolitan Hospital Sunday Fund. For it is in the wards of our hospitals and in the laboratories of our medical schools that the skill and experience are gained which are demanded from the medical man by the whole community. And not only does the individual benefit, but collectively the gain is immense, for the general improvement in public health which has so characterised the later years of our era is due largely to the facilities for experimental study in chemistry, in bacteriology, and collateral sciences which are afforded by laboratories attached to or worked in connexion with our hospitals. Again, the coöperation of hospitals with the large army of workers in the sphere of tropical diseases has helped to make vast tracts of our colonial possessions inhabitable by the white man, thus extending the Empire and adding to our prosperity by increasing trade. These are only some of the great benefits which have accrued under our voluntary hospital system, making it, whatever may be its faults and failures, of inestimable benefit to all classes. To this record, however, must now be added the wonderful response to the call of war. Without the splendid initiative and organising power of the managements of our leading institutions this response could not have been made, and the great funds which collect on behalf of these charities have played a fine part in the national struggle by helping to keep the hospitals at full working strength. The Metropolitan Hospital Sunday Fund is one of the three great agencies which help to maintain the London hospitals, its main purpose being to collect money from the various religious congregations. Primarily the appeal is made through the churches, chapels, and missions of London, but in reality the large sums that are yearly distributed among the hospitals are made up of congregational collections, with the addition of private donations and legacies. As this second source of income must of necessity fluctuate it is of the greatest importance that every effort should be made to ensure an adequate collection on Hospital Sunday. Of recent years congregational collections have shown a steady decline, owing in a great measure to the fact that a large number of well-to-do people spend the week-end out of town. Appeals have been made to absent church members both before and after Hospital Sunday, but the result has not been at all satisfactory. The week-end habit should not, however, operate to the same extent this year, for there is more serious work on hand than these recurring holidays imply. Large calls have been made already upon the charitable in connexion with the war relief funds, huge liabilities are piling up ahead of all of us, and many of those from whom help was always forthcoming are serving their country at the front. These things will certainly militate against the Metropolitan Hospital Sunday Fund this year, and unless special efforts are made the collection which takes place to-morrow may suffer.

But never has the need for help been greater in the hospitals of the metropolis and never has it been more deserved than at the present time. The hospitals have been deprived of many of their valued workers who are giving their services directly to the men who are fighting abroad, while those who remain at home have been working at serious pressure to make up for the deficiency thus created. Yet, in spite of this, not only have the sick poor been attended to with the care and efficiency of normal times, but, in addition, thousands of the sick and wounded from the front have received devoted care in these institutions, removed from the terrible environment of the war area. This all means increased work, carrying with it an increased expenditure which has taxed the resources of the managers of our voluntary hospitals in some cases to breaking strain; and such facts should suffice to bring home to everyone who can help even in the smallest way the crying need for an increased financial support of the metropolitan hospitals. Without the aid of hospitals as centres for the training of nurses there would have been a deficiency in an important auxiliary to all medical and surgical treatment, and our hospitals have made many sacrifices in order that a sufficient number of nurses might be trained at short notice. To prompt action in this direction many must owe their restoration to life and health. For many years the management of the Metropolitan Hospital Sunday Fund has placed before itself the ideal of collecting for the medical charities of London and the vast outlying districts the sum of £100,000 on each Hospital Sunday, but this total has never been realised. The present moment is an admirable one for the public to show their gratitude to the London hospitals by placing at the disposal of the managers of the Metropolitan Hospital Sunday Fund a larger sum than usual—why not their ideal £100,000?—with which to lighten the burden of debt which presses so heavily upon many institutions.

Medical Organisation and the War.

Two great questions are concerned when we consider medical organisation in respect of the war. They are, first, the engagement of a sufficient personnel, and, secondly, its employment to the best advantage. The first question has been receiving the close attention of the medical authorities at the War Office, an Emergency Committee of the British Medical Association is considering it, and a strong Emergency Committee, with Dr. NORMAN WALKER as convener, has taken in Scotland practical steps towards answering it. But the second question is of equal importance, if only because a personnel that is working to the best advantage with its material is more economical in its employment of men than one where there is overlapping, or where there are many round pegs in square holes. The position of the medical service with the Expeditionary Forces depends, as it always has done, on the military situation. But great experience has now been gained. Tried men have been collected, and to a certain extent these are being detailed for the posts most suited to their capacities, so that some large general lessons in pathology are being learned. There remains, however, in the minds of many a feeling that all the splendid work might be more fruitful, might be simplified, and at the same time have its value disseminated, if there were some general supervision of work done; possibly it would then be found that men could be spared in some places for more suitable work in others.

In the hands of such surgeons as Sir ANTHONY BOWLBY and Sir GEORGE MAKINS, of such physicians as Sir WILMOT HERRINGHAM and Sir JOHN ROSE BRADFORD, each of whom is also a tried organiser and man of affairs, we may be sure that nothing has been wanting in the hospital treatment through the various areas that organisation would ensure; but, as we have pointed out before, each centre must work largely upon its own lines, as there is no recognised scientific supervision, while official means of intercommunication have not been established. At any given hospital as its staff changes men come in who have not had experience on the spot, and there is no machinery by which to place them in immediate possession of the lessons learned by their predecessors. The tendency to revert to classical treatment is therefore inevitable, and ground may have to be gone over again with clear waste of energy in the many directions in which classical treatment has to be modified to meet new and unexpected conditions. This may be going on in many localities, while it is clear that local experience will vary and local standards of practice will vary also, so that the lesson to be learned in one centre is not the same necessarily as that to be learned at another. It speaks volumes for the high standard of medical and surgical practice of this country that so many hospitals should have been staffed with good result by officers who have relied upon their own initiative for treatment, but general supervision from the centre would none the less be welcome. It is difficult to see how men at any given hospital can tell whether their patients, under the treatment which is being adopted, are doing as well as similar patients in other hospitals. There is not a definite medium for the interchange of knowledge and it is hard to say whether certain cases are being treated at the most suitable points in the lines or whether more sorting of material would not be of advantage both to medical men and to patients. If there were regular collecting and collating of results by an advisory body whose business it would be to inspect treatment all along the lines, from what is practically the front through the intermediary hospitals to the base hospitals, we feel that practical results would follow. There is no definite suggestion that the medical service is not good, and in numberless directions its achievements speak for it as wonderfully efficacious, resourceful, and devoted; the point is that its proven virtues would operate more promptly and widely under some central control. The work done cannot all be equally high in standard. Where it is not good at some point in the periphery central control would reinforce it. Where it is good the peripheral efforts would be recognised, the lessons learned in that place would be applied in another, investigation and scrutiny would be followed by coördination. In short, a service with automatic limbs would be endowed with a brain. In an epilogue to the address by Sir ALMROTH WRIGHT published in THE LANCET in April, he suggested that an Advisory Committee having much the same functions as those that have been indicated should be instituted. This body, to cover the field, should consist of a surgeon, a physician, and a bacteriologist. To these we would add a second surgeon to act as secretary and registrar to the committee, and we cannot help thinking that the Director-General of the Army Medical Service would find the recommendations of such a body of great assistance. Nothing, it must be clearly understood, can be done without the approval or order of the Director-General of the Army Medical Service. But such an Advisory Committee would, we are sure, enable him to discharge his onerous and important duties with less chances of waste of time, with less risks of re-duplication of labour, or of overlapping. The Director-General, while absolutely retaining his own authority, and retaining also the right to be advised by other distinguished officers, would look to such a committee to supply him with the results of experience and practice all along the lines, when it is quite likely that there would emerge general recommendations for treatment analogous to those which already prevail in the cases of tetanus and of typhoid fever. The Advisory Committee would be in a position also to suggest the best distribution of cases, so that we should not hear that "so many" cases had been relegated to a certain man, but rather that "such and such" cases had found their way to him.

We make these suggestions with the less diffidence because we know that something in the indicated directions has found favour in the sight of high authority. There is no intention to imply that the medical work with the Expeditionary Forces has not been good, for it is admitted on all hands that the Royal Army Medical Corps has earned the gratitude of the country and that the coöperation of civilian medicine and surgery has been valuable in the highest degree. But the war has already been a long one, and may continue for some time. Many therapeutic lessons have already been learned, and surely it would be advantageous to make a move in organisation which would place these lessons fully at the disposal of future workers.

Annotations.

"Ne quid nimis."

PRECAUTIONS AGAINST AERIAL ATTACKS.

THE dangers of an aerial raid may be said to be threefold. There is, first, the actual explosion of the dropped bomb which may instantly destroy life by the intense concussion formed, this acting directly or indirectly; there is the chance of poisonous gases being released; and, lastly, the incendiary bomb may cause a serious outbreak of fire. It is well to be on our guard against these contingencies. Of course, little or nothing can be done in the first contingency. Concealment in a well-protected shelter, as in an underground cellar, may be possible for some people in some circumstances, but the number of people to whom the advice applies is small. The protection of the household against poisonous or asphyxiating gases discharged by bombs at once suggests the same measures taken by our soldiers in the trenches. It is well to remember that most, if not all, asphyxiating gases are acid in character and that therefore they can generally be neutralised by the use of an alkali. The available alkali in every house is common washing soda. The bath towel made of netting with a big mesh when soaked in a 10 per cent. solution (1 lb. in one gallon of water) of this salt, and the excess squeezed out, would enable, in all probability, a person to breathe in an atmosphere contaminated by chlorine, nitrogen oxides, or sulphurous acid gas. The towel should be in double or quadruple layers so as to expose as much as possible the contaminated air to the neutralising action of the alkali. A dish-cloth or a well-squeezed-out sponge soaked in the same alkaline solution would answer equally well. The sponge forms a very comfortable and efficient respirator if thoroughly squeezed out before application. It adapts itself well to the mouth and nose. The breathing should be slow, inwards through the mouth and outwards through the nose. The protection of the eyes, unless special goggles are used, is more difficult, the simplest precaution being to shut them tightly in the event of the gas causing extreme irritation, until a purer atmosphere is reached. In any case it is well to learn how to move in an enforced darkness in one's own house. In the event of an outbreak of fire the sooner steps are taken the better chance there is of keeping the outbreak local. There is nothing so effectual as a wet blanket thrown over the scene of conflagration, followed by the application of buckets of water on the blanket. We strongly advise all those who possess gardening hose to have it near at hand for use in the house. Small fires can be quenched by throwing upon them a solution of ammonium chloride mixed with common salt; this when used at the outset is often effective. There are many chemical extincteurs on the market, some good, some worthless, but all requiring more or less technical management. It is doubtful whether the public should be advised to incur the outlay which their installation in the house involves, especially as a pail of ammonium chloride solution and a syringe would probably meet the case just as well. The simpler the precautions are the better, for as a rule simplicity in the matter of appliances generally means much less nervous handling in moments of excitement and a more effective dealing with the situation. The public would be well advised also if on retiring they turned off all lighting services at the meter and for night use reverted to candles. The house might be placed in great danger if gas or electric mains were damaged by an explosion or fire. It is well to remember what potentialities these services mean when they are let loose. The switch and the tap will control them, but if any part of the system is destroyed behind these the outbreak may well defeat all attempts to subdue it.

BACTERIAL FLORA OF WOUNDS.

THE attention of bacteriologists has naturally been prominently drawn to the bacterial infection of wounds produced during the present war. Investigations are being carried out as to the nature of the organisms present both in this country and in France. The results hitherto obtained are interesting, but can only be considered as experimental and preliminary to a combined investigation of scientists and surgeons. The National Research Committee is rendering valuable service by contributing grants towards the expenses of such inquiries. In another column we publish a communication from three observers who have been working on the bacterial flora of wounds, Dr. L. S. Dudgeon, Mr. A. D. Gardner, and Mr. F. Bawtree. The investigation was carried out in this country so that no records are given which refer to the type of bacteria found directly after injury. It is interesting to note that there is the closest similarity between the bacteriology of severe injuries of the soft parts produced by shrapnel and infected by manure and a street accident infected by horse-dung. There is usually infection of the damaged tissues with the B. aerogenes capsulatus, streptococci, and coliform bacilli. The authors express the opinion that the mere presence of the B. aerogenes capsulatus is not the important factor in a wound, but it is the presence of this organism in tissues which are under considerable increase of tension that is of such extreme importance. This would help to explain the beneficial results obtained by freely laying open the parts affected. Especial attention is paid to those wounds in which pathogenic anaerobes were found. Twenty-one wounds yielded cultures either of B. tetani or of B. aerogenes capsulatus, or of both. With a single exception every wound was also infected with aerobic bacteria in association with the anaerobes. The frequency with which B. coli appeared with B. tetani suggests that its presence may be particularly favourable for the survival of this anaerobe. Although no reference is made to treatment in this paper, the opinion is expressed that the prophylactic injection of antitoxin has been the means of saving the majority of the patients from serious disease arising from wound infection. The communication is of considerable interest from a bacteriological point of view, and the scientific investigation is preliminary to the application of measures intended to antagonise infection. We trust that a practical outcome of the research will soon be forthcoming.

ROYAL COLLEGE OF SURGEONS OF ENGLAND: THE ELECTION TO THE COUNCIL.

ON Thursday, July 1st, a meeting of the Fellows of the College will be held for the purpose of electing five members of the Council. The vacancies are due to the retirement in rotation of Sir Rickman J. Godlee, Mr. C. W. Mansell Moullin, Mr. Charters J. Symonds, and Mr. Charles Ryall, and by the death of Mr. C. B. Lockwood. There are 24 members of Council, and three of these retire each year, but Sir Rickman Godlee did not retire last year as he was President at the date of the election. The following list gives the dates at which the several members will retire:—

1916: Sir A. Pearce Gould (first elected 1910); Sir W. Arbuthnot Lane; Mr. W. F. Haslam.

1917: Mr. W. Harrison Cripps (first elected 1905); Sir W. Watson Cheyne, the present President (first elected 1897); Mr. J. Stanley Boyd.

1918: Mr. Bilton Pollard; Sir J. Bland-Sutton.

1919: Sir Berkeley G. A. Moynihan; Sir G. H. Makins, Vice-President (first elected 1903); Mr. L. A. Dunn.

1920: Mr. D'Arcy Power; Sir F. S. Eve, Vice-President; Sir Anthony Bowlby, K.C.M.G., Vice-President (first elected 1904).

1921: Mr. J. Ernest Lane; Mr. H. J. Waring.

1922: Mr. C. A. Ballance, M.V.O. (first elected 1910); Mr. W. Thorburn; Mr. W. McAdam Eccles.

For the 5 vacancies there are 9 candidates. Of the retiring candidates only two, Mr. Charters Symonds and Mr. Charles Ryall, offer themselves for re-election. The other candidates are the following, the figures in brackets representing the date of obtaining the Fellowship:—Mr. J. B. Lawford (1885), Mr. T. H. Openshaw (1886), Mr. H. B. Robinson (1887), Mr. W. G. Spencer (1887), Mr. F. F. Burghard (1888), Mr. H. F. Waterhouse (1890), Mr. P. Macleod Yearsley (1893).

A CASE OF GENERALISED PNEUMOCOCCAL INFECTION.

A REMARKABLE case of this nature is reported by Dr. D. A. Cameron in the *Medical Journal of Australia*, vol. i., 1915. A girl, aged 7 years, was taken ill on the morning of Oct. 22nd, 1914. She had severe pain in the abdomen, sickness, and diarrhœa. The temperature was 104° F., pulse 140, respirations rapid, and there was general abdominal tenderness. Pneumonia or appendicitis was suspected. Twelve hours later the first operation was performed. There was considerable fluid in the abdominal cavity and the appendix was much inflamed. The fluid yielded a pure culture of pneumococcus. The temperature afterwards still remained high, though drainage was satisfactory. Pain was complained of in the right shoulder. A week later cough developed. The second operation took place on

Nov. 4th, following aspiration, and 14 ounces of pus were removed from the right pleural cavity; this again showed pneumococci. Following the suggestions of the symptoms, operations were considered necessary for left-sided empyema, containing four ounces of pus (Nov. 13th); for intestinal obstruction revealed at operation (Nov. 24th) as due to strands of peritoneum dragging upon the junction of the small intestine and the colon; for a third collection of pus in the right upper chest, and apparently having no connexion with the lower focus previously drained (Dec. 13th). This relieved the pain in the right shoulder. Finally, on Jan. 18th, the last operation, upon the right hip-joint, released more pus, and from that time onwards the child, wasted to a skeleton and throughout having pyrexia, made an uninterrupted recovery. It is remarked that vaccines proved of no avail. Notable also is the fact that no pyæmia ensued, in spite of the obviously generalised distribution of the infecting organisms.

THE SPREAD OF TYPHUS FEVER BY LICE.

READERS of that extraordinarily vivid book the "Mémoires du Sergent Bourgogne," giving the report of an eye-witness and victim of the disasters of Napoleon's Russian campaign in the year 1812, will remember the horror with which the author found himself suddenly infected with vermin a few days after the French retreat from Moscow had begun. The infection was picked up, he says, from some reed mats on which he went to sleep in the village of Dorogoboui; as soon as he felt the itching he got up, stripped, and threw his shirt and trousers on the fire. The vermin exploded in the flames like the fire of two ranks of infantry; but for the next two months the gallant sergeant was never free from vermin, and in consequence his Mémoires contain repeated longings for clean linen. General de Ségur, who wrote a well-known account of Napoleon's Russian campaign from the point of view of a staff officer, concerned himself with such things as the European political situation, Napoleon's plans and conversation, or the disagreements between the various members of his staff, but hardly touched upon such lowly matters as pediculosis among the French troops. Yet the subject was one of the utmost importance, had he known it; in its retreat from Moscow Napoleon's Grand Army was harassed by a severe epidemic of typhus fever carried by vermin, and the soldiers forming the wreck of the Grand Army spread death and destruction by typhus fever right and left wherever they passed through Germany on their way from Russia. As Dr. A. Rose points out in "Napoleon's Campaign in Russia" the position of affairs is clearly shown in the report of Dr. Krantz, a Prussian army physician attached to the Grand Army, published in 1817. The lice carried typhus fever with them, and soldiers showing no sign of the disease were capable of infecting the families of civilians in whose houses they were quartered. The rapidity with which the infection spread is indicated by facts such as the following. In the 1st East Prussian Regiment of Infantry there was not a single case of typhus fever until it had marched for 14 miles on a highway along which the French had passed, while after this there were 15 or 20 cases in every company of 150 men. Dr. Krantz had most interesting observations to record on the treatment of typhus fever. The open-air treatment, inevitable in the case of soldiers on the march, had a mortality of only 2 or 3 per cent., while the patients treated in hospitals died in large numbers, also infecting and killing the physicians and nurses who attended them. Soldiers presenting the headache, nausea, and vertigo that are the first symptoms of typhus fever, were dressed warmly and put into wagons and covered with straw, with other precautions to avoid frostbite. At night they were quartered in isolated houses to avoid the spread of infection. It was remarked that the open-air method of treatment abolished the stage of convalescence after the attack was over. Three days after the patients had been free from fever for 24 hours they were fit for half a day's march or more. Dr. Rose, in a recent issue of the *Medical Fortnightly*, St. Louis, lays great stress on the importance of killing the lice that seem even nowadays, to judge by what one hears from the front, to be inseparable from fields of battle, and he quotes on this point from a circular recently issued by the German Imperial Board of Health. It is obvious that powerful parasiticide drugs must be used to kill the lice, in cases where baking or boiling the infected clothes, or, as Virgil puts it, *Infectum eluitur scelus, aut exuritur igni* is a counsel of perfection and impracticable. The Board recommends for this purpose sabadilla vinegar (containing veratrine), kerosine, eucalyptus oil, and balsam of Peru. Weyland in the Franco-Prussian war of 1870 found benzine excellent for this object. The clothes were exposed to benzine vapour in a tightly closed box for two or three hours. A recent number of the *Deutsche Medizinische Presse* speaks of asafœtida and naphthaline, regretting that no satisfactory prophylactic and no curative remedies have yet been found. Dr. Rose thinks that benzine or gasoline will probably prove the most serviceable. The German State railways have an excellent plan for cleansing their railway carriages. The whole carriage is run into a large iron cylinder, which is hermetically sealed; then the air is exhausted from the cylinder and its contents are warmed up (far short of the boiling point of water) by steam pipes. The lice infecting the upholstery of the carriage can survive the exposure to a partial vacuum, but when the heat is turned on their body fluids are evaporated at the low pressure, and so they die the death of desiccation.

THE DEATH-RATES DUE TO DISEASE OF THE HEART, ARTERIES, AND KIDNEYS.

IN the United States of America the death-rates due to chronic heart disease, arterial disease, and renal disease all show considerable relative and absolute increments in the last few decades. Excluding valvular disease of the heart and acute nephritis, Dr. A. E. Shipley in the Bulletin of the Department of Health, New York, argues that all these conditions are promoted by (1) environmental circumstances demanding a persistent hyperactivity of the circulation; (2) the retention of toxic products of metabolism in the blood; and (3) senile change, so-called. Examining the death-rates for America in 1912 he finds that one-fifth of all deaths were due to diseases of the cardio-vasculo-renal type. In 1870 the death-rate from all causes was under 29 per 1000, in 1912 it was under 15 per 1000, but in 1912 the death-rates from these disorders in persons aged 45 or more had increased by from 100 to 300 per cent., as compared with the death-rates recorded at these ages in 1868. Dr. Shipley asserts that these disorders are largely preventable, and calls for special measures to educate the public in the avoidance of the conditions known to promote the occurrence of these degenerations. Among the things to be avoided are undue mental strain and worry in business, abnormal social activity, over-eating, the indulgence in too much protein food, excessive alcoholic indulgence, lack of fresh air and exercise, chronic constipation and intestinal stasis, and the vascular degeneration so often associated with such diseases as syphilis, rheumatism, lead poisoning, and the like. Emphasis should be laid on the importance of drinking water as an aid to ridding the blood of toxic substances that raise the blood pressure. Adults should undergo medical examination from time to time, so that the beginnings of these degenerations may be detected and treatment for them instituted in their early stages. Dr. Shipley develops a comprehensive scheme for educating the public in these matters, to be managed by local health departments on much the same lines as tuberculosis campaigns or pure milk campaigns have been managed in the past.

LAVAGE IN CARBOLIC ACID POISONING.

IN carbolic acid poisoning lavage with various solutions has been recommended, and two substances—alcohol and sodium sulphate—have been particularly recommended, apparently on rational grounds. In the Johns Hopkins Hospital Bulletin Dr. David I. Macht has published an important experimental investigation on the subject and shown that alcohol is not only useless but injurious. Its use is due to a fallacious deduction from the fact that it is beneficial in carbolic acid burns. Alcohol was introduced as an antidote for carbolic acid in 1899 by Dr. S. D. Powell, of New York, who used to demonstrate his view by washing his hands in pure carbolic acid and then in alcohol, and even by filling his mouth with the acid and quickly rinsing with 95 per cent. alcohol. Subsequently isolated cases were recorded as illustrations of the value of alcohol. With regard to the use of sodium sulphate, contradictory researches have been published. In the higher animals the first symptoms of carbolic acid poisoning are weakness and a peculiar muscular tremor. These are soon followed by clonic convulsions, collapse, coma, and death. There is very little pain, as the central nervous system is quickly paralysed. Dr. Macht introduced liquefied carbolic acid, both in concentrated solution and in various dilutions through a stomach tube into various animals and washed out the stomach at different periods after the appearance of symptoms with solutions or suspensions of various substances—egg albumin, alcohol, sodium sulphate, sodium sulphite, and syrup of lime. Albumin proved of little use and sodium sulphite too poisonous. Lime water and syrup of lime, recommended in the hope of forming an insoluble compound, were found unsatisfactory. In cats the success of lavage was found to depend on the amount of carbolic acid given, the time of lavage, and the solutions used. After small, though lethal, doses, washing out the stomach thoroughly with either plain water or a concentrated solution of sodium sulphate on the appearance of convulsions (three to five minutes after ingestion) saved the animals in most cases. Lavage with solutions of alcohol was followed by death more often than by recovery. After large doses of carbolic acid prompt lavage with alcohol was followed almost invariably by death, plain water also failed, but solution of sodium sulphate gave the best results—survival for a time or recovery. After later lavage with alcohol or plain water the animal invariably died, but after lavage with sodium sulphate it occasionally recovered. Dogs withstood carbolic acid better than cats, and could be saved by immediate lavage irrespective of the medium used. After larger doses immediate lavage with sodium sulphate or plain water sometimes saved the animal, while lavage with alcohol was almost always followed by death. In late lavage (about 15 minutes after ingestion) sodium sulphate gave the best results and plain water the next, while the use of alcohol was almost invariably followed by death. Dr. Macht agrees with Tauber that sodium sulphate does not act chemically, but by hindering absorption and possibly also by purgation. Magnesium sulphate can be used for the same reasons, but the possible depressing effect of the magnesium ions in case of absorption is a disadvantage. Further experiments showed that animals which had previously been poisoned with alcohol withstood carbolic acid better than others. Possibly this was due to the greater affinity of the alcohol for the nerve cells which prevented the carbolic acid from acting on them. On the other hand, alcohol given after ingestion of carbolic acid simply promotes absorption, as it is an excellent solvent of the latter. This is confirmed clinically, for of 10 cases mentioned by Falck in which carbolic acid was taken in various alcoholic drinks 9 were fatal, whereas in 17 in which the acid was simply taken by mistake 13 were fatal. The point is important, for the recommendation of alcohol as an antidote to carbolic acid is to be found even in text-books.

NYSTAGMUS AND LABYRINTHINE STIMULI.

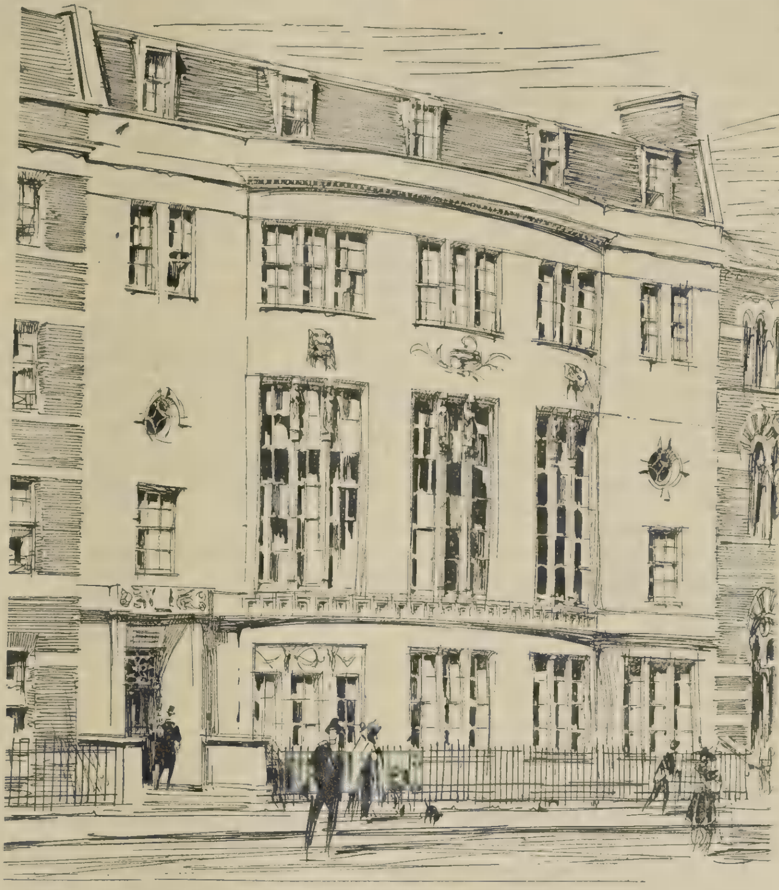
FOR nearly two decades the problems connected with the physiology and pathology of the association of eye movements—nystagmus—and labyrinthine stimuli have attracted the attention of aurists, neurologists, and physiologists. Of later years the tracts along which these impulses pass from the ear to the eye, as well as a clearer and more definite localisation of the nerve centres which receive these impulses, have been the subjects of careful investigation. But at the same time much speculative matter has been put forward, some based on most ill-defined premisses. All good earnest scientific work is to be welcomed, the more so on account of the speculative character of much modern teaching. Dr. J. Gordon Wilson and Dr. F. H. Pike have recently given us a very important contribution on this matter, a series of laboratory experiments dealing with the afferent and efferent tracts of the stimuli and their effects. These are to be found in the records of the American Otological Society, this particular paper being delayed by the fact that the illustrations were being reproduced on the continent of Europe. The value of the experiments appears to be great, showing amongst other things that "lesions of the cerebral hemisphere on the side of the slow deviation of the eyes abolish or reduce the quick component."

THE Seventh International Congress for Obstetrics and Gynæcology, which was to have taken place this autumn in New York, will not be held on account of the political situation existing in Europe. The American committee has decided to postpone the date of meeting of the Congress until September, 1917.

THE NEW BUILDINGS OF THE GENERAL MEDICAL COUNCIL.

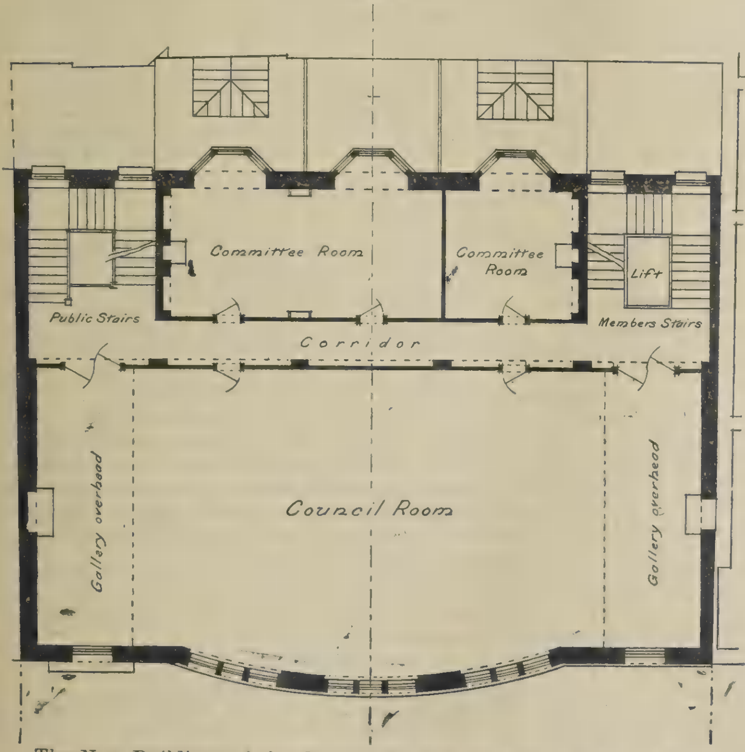
THE first meetings of the General Medical Council took place at the Royal College of Physicians of London, and subsequently a registration office was opened in Soho-square. In 1874 the Council obtained from H.M. Office of Works the premises at 299, Oxford-street, which were formerly occupied by the Royal College of Chemistry, and in 1895 the Council purchased the freehold of the site and of the ground behind it, which runs through to 16, Hanover-square. For some time it has been considered that it would be advantageous to dispose of the Oxford-street site if a suitable one could be obtained elsewhere. Not only might the Council's income be thereby increased, but it would be possible to put up a new building more suitable to the Council's requirements. Although a council chamber had been built on and a storey added to the old building, the premises were by no means convenient. Not only was the office accommodation inadequate, owing to the large extension of the membership and work of the Council, but during the session it was quite impossible to provide proper rooms for the legal advisers, the medical profession, the witnesses, and such members of the general public who may be present during the proceedings.

FIG. 1.



The New Buildings of the General Medical Council: Front elevation.

FIG. 2.



The New Buildings of the General Medical Council: First-floor plan.

The Oxford-street portion of the site has now been disposed of, and a new site has been taken on the Howard de Walden estate in Hallam-street, which lies between Portland-place and Great Portland-street, parallel to these two thoroughfares. The street is one which has no direct openings at either end, and is therefore not much used for through traffic. The whole of it is now being rebuilt, and in about three years' time, with the exception of the Council's building and the Jewish Synagogue next door, it will consist of residential flats. The new building has been designed by Mr. Eustace Frere, A.R.I.B.A., of 1, Lincoln's Inn-fields, and the contractors are Messrs. Chinchen and Co.

The front elevation is shown by Fig. 1. The front is of Portland stone, with a central bay extending nearly to the full height of the building. On entering the visitor will find himself in a large hall, round which are the registration office, rooms for the President and Registrar, and separate cloak rooms and lavatories for the members of the Council and the public. At each end of the building is a staircase, one of these being for the public and the other for members. A lift is also provided for members, who thus have access to all parts of the building independently of the passages intended for the public, except in the entrance hall itself. The Council chamber extends the full width of the building on the first floor, and in rear of it are two committee rooms; one of these can be subdivided by a movable partition and retiring rooms for complainants, defendants, and the legal profession will thus be provided. The Council chamber occupies in height the space of two floors; there will be a gallery at either side of it and the room will be panelled in oak. On a mezzanine floor at the back of the upper part of the Council room are two large committee rooms on a level with the galleries; these will provide accommodation for the press when the Council sits *in camerâ*. Above this again is a members' luncheon room and a smoking room, together with another committee room, and at the top are quarters for the caretaker. The war has caused a great rise in the cost of building materials and labour, and it has therefore been found necessary to postpone the installation of some of the decorative features in the original design, such as the panelling of the Council chamber, but it is hoped that these may be added in a few years' time.

The new building will probably be occupied before the end of this year, but the next two sessions are likely to take place in the Oxford-street premises.

REPORT OF THE ADVISORY COMMITTEE FOR THE TROPICAL DISEASES RESEARCH FUND FOR 1914.[1]

AS was pointed out last year when commenting upon the annual report for 1913, the advisory committee of the Tropical Diseases Research Fund, which was constituted by the Secretary of State for the Colonies in 1904, continues to be greatly hampered in its good work by the insufficiency of its financial resources. The income for 1914 amounted to £3745, of which the Imperial Government contributed £1000 and the Government of India £500, the remainder being made up by contributions from the Dominion and Colonial Governments. The expenditure was £4250, so that there was an excess of £505 on the wrong side. This deficiency had again to be made up by drawing upon the accumulated balance of the fund which is now reduced to £750; so that this method of meeting the annual deficiency must soon come to an end.

The Expenditure of the Fund.

The expenditure comprised a grant of £1450 to the London School of Tropical Medicine; of this amount, £1200 were expended in payment of salaries and the maintenance of the laboratories of the teachers and investigators of helminthology, protozoology, and entomology, £250 being also given as a contribution towards the investigation of schistosomiasis carried out by Dr. R. T. Leiper in the Far East. The Liverpool School of Tropical Medicine received £1200, of which £500 were spent on research work on trypanosomiasis, £250 on research work on parasitology and helminthology, £250 on entomological research, and £200 on malaria investigation. A sum of £850 was given to the University of London, £750 of which was expended in paying the salary of the professor of protozoology, and on the application of the University £100 were granted towards the salary of the professor's scientific assistant, Dr. H. M. Woodcock. To the University of Cambridge £750 were paid, £100 of which were given in respect of the research studentship in medical entomology, £100 towards the salary of an assistant to the Quick professor, £100 towards the payment of a helminthologist, £50 towards the salary of a demonstrator in medical entomology, and £100 for the general expenses of the Quick laboratory. A special grant of £300 was made towards the expenses of sending Dr. E. Hindle to Uganda and Nyasaland to carry out research work there, but owing to the war the expedition was postponed, and the £300 will remain earmarked for this work.

Statistical Returns.

Appended to the report are the statistical returns received from certain colonies and protectorates with regard to mosquito-borne diseases, supplied in accordance with the circular of the Secretary of State dated Dec. 20th, 1910. Reports are also appended of the work done by the London and Liverpool Schools of Tropical Medicine and reports of the professor of protozoology in the University of London and his assistant; also a report by Professor G. H. F. Nuttall on the work done in the Quick Laboratories. Certain reports on work done at various colonial laboratories are also appended, and one by Dr. Louis W. Sambon on Dermatobia hominis in the West Indies, where he has been recently conducting inquiries. By arrangement a résumé of the Annual Report of the Gordon College Research Laboratories at Khartoum is likewise included.

Reports on Antimalarial Measures in the Crown Colonies and Protectorates, &c.

These reports are preceded by a note furnished by Professor Sir Ronald Ross on the Prevention of Mosquito-borne Diseases in the Colonies, along with a suggested form of return. The colonies, the reports of which are printed in the appendix, include the Windward Islands (St. Vincent), Hong-Kong, the British Solomon Islands Protectorate, South Africa, the Leeward Islands (Antigua, St. Kitts-Nevis, Dominica, and Montserrat), Nyasaland, the Straits Settlements, Zanzibar, Mauritius, the Northern Territory of Australia, and Trinidad. The committee observe with satisfaction that these reports have been prepared with great care, and they call special attention to the valuable reports supplied by Hong-Kong, Zanzibar, and the Straits Settlements.

Report of the Professor of Protozoology, London University.

The work of Professor E. A. Minchin included further researches, with the assistance of Dr. J. D. Thomson, on Trypanosoma lewisi and its immediate host the rat-flea, the complete memoir of which, embodying all the results and fully illustrated, has been sent to the *Quarterly Journal of Microscopical Science* for publication. A résumé of the report, however, is given by Professor Minchin, and this is divided into three parts. Part I. contains an introduction and a description of the technique employed, and the anatomy and histology of the flea. Part II. contains the results of the observations made, and Part III. the results of the experiments carried out. The development of the trypanosome in the flea is described, as also the experimental results with regard to the transmission by the flea and other kindred problems.

Report by Dr. H. M. Woodcock.

Dr. Woodcock, assistant to Professor Minchin, reports on the work done by him during the year ended June 30th, 1914, under the headings of (1) Research and (2) Assistance to the Professor and in the Department. Under the first he deals with flagellates occurring in the common British mosquito, Culex pipiens, and as to the second he refers to demonstrations which he gave in connexion with Professor Minchin's course of lectures on the Protozoan Parasites of Man. Dr. Woodcock also rendered considerable assistance to the workers in the laboratory.

Report on the Work of the Quick Laboratory, Cambridge.

Professor Nuttall gives an account of various papers to the number of 10 published by workers in this laboratory during the year, and incidentally mentions that the work of his department has been greatly disturbed by the war. A number of his students and assistants have obtained commissions and are serving in the army. One has been killed in the fighting which took place in Nyasaland. Miss Porter, D.Sc., has resigned her post of helminthologist upon her appointment to a Beit Memorial Scholarship.

---

[1] Report of the Advisory Committee for the Tropical Diseases Research Fund for the Year 1914. Presented to both Houses of Parliament by command of His Majesty. London. 1915. Printed under the authority of H.M. Stationery Office. Pp. 248. Price 2*s.* 3*d.*

Report of the London School of Tropical Medicine.

This includes reports by the entomologist, the helminthologist, and the protozoologist, for the two half-years ended Oct. 31st, 1914, furnished respectively by Lieutenant-Colonel A. Alcock, I.M.S. (retired), Dr. R. T. Leiper, and Dr. C. M. Wenyon. Dr. Leiper's report is addressed from China, whither he had gone as Wandsworth scholar, accompanied by Surgeon E. L. Atkinson, R.N., for the purpose of studying the mode of spread of trematode infections of man, especially bilharziasis, a special report on which is given and further particulars promised later. Dr. Wenyon has resigned his post, and has been succeeded by Dr. J. Gordon Thomson, formerly of the Liverpool School of Tropical Medicine. The operations of the London school have been much disturbed by the war and by the departure of some of the teachers who have joined the forces in the field.

Report of the Liverpool School of Tropical Medicine.

In this are contained reports by Professor J. W. W. Stephens, Professor R. Newstead, and Professor Warrington Yorke, and by Dr. H. B. Fantham and Dr. B. Blacklock, of the work done in their various departments. A summary of the scientific papers contributed by members of the staff of the school is appended. At the Runcorn Laboratories Dr. Blacklock has been engaged for some time upon investigations in connexion with Trypanosoma cruzi, the South American trypanosome of man. As this parasite is transmitted by a reduvid bug experiments were made to ascertain if the common bed-bug might also act as a carrier of this disease. Dr. Fantham among other researches continued his investigations on bronchial spirochætosis.

Report from the Wellcome Research Laboratories, Khartoum.

This report deals with the work carried out by the Bacteriological Section, and that by the Entomological Section concerned with subjects of interest in tropical medicine, after the resignation of Dr. Andrew Balfour, C.M.G., and under the directorship of Dr. Albert J. Chalmers.

Observations on the Life History of Dermatobia Hominis.

Dr. Louis W. Sambon, in the course of a recent visit to the West Indies, found opportunities for examining several cases of cutaneous myiasis in man and animals. He also collected some interesting information regarding the bionomics of Dermatobia hominis, a warble-fly, the larva of which is a common parasite of man in certain regions. His observations were made in Colombia, British Guiana, and Trinidad, and his report, which is illustrated, makes very interesting reading. He appends to it a long list of references on the subject.

Reports on Work Carried out in Colonial Laboratories.

The report from the Institute for Medical Research, Kuala Lumpar, Federated Malay States, among other things deals with beri-beri, leprosy, and blackwater fever from the scientific standpoint, and as an "annexure" Dr. H. Fraser and Dr. W. Fletcher furnish a contribution on "The Bacillus Lepræ: Has it been Cultivated?"[2] The Hong-Kong Bacteriological Institute supplies a report on investigation of the mosquitoes in that colony, in which the stegomyia fasciata is definitely stated to be present, especially on the Kowloon side of the harbour. Dr. Aldo Castellani gives a report on the very varied and valuable work carried out by him at the Clinic for Tropical Diseases and at the Bacteriological Institute, Ceylon. Lastly, Dr. H. Harold Scott presents an interesting report for the year ending Sept. 30th, 1914, on the work done at the Pathological Laboratory, Public Hospital, Kingston, Jamaica.

---

[2] THE LANCET, Sept. 27th, 1913, p. 918.

DONATIONS AND BEQUESTS.—By the will of the late Sir James Rankin, first baronet, of Bryngwyn, Hereford, the testator bequeathed £1000 to the Herefordshire General Hospital.—The Royal Westminster Ophthalmic Hospital has received from the trustees of the Zunz Bequest a further donation of £300.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE undermentioned have been granted temporary commissions as Surgeons in His Majesty's Fleet: Stanley Ninian Wright (dated June 3rd), Harold Oliver Martin (dated June 4th), Charles Milwyn Burrell (dated June 5th), Gerald William Mooney, and John Arnold Fairer.

The following appointments have been notified:—Fleet-Surgeon: H. J. Hadden to the *President*. Temporary Surgeons: M. Fawkes and H. H. Gellert to the *President*, J. T. E. Evans and G. W. Mooney to the *Pembroke*, and J. A. Fairer to the *Victory*, the two last-named officers for Chatham and Haslar Hospitals respectively; J. Lambert to hospital ship *Rewa*, and J. S. Kennedy to the *Monarch*.

ROYAL NAVAL VOLUNTEER RESERVE.

Surgeon Ebenezer Snell has been promoted to the rank of Honorary Staff Surgeon. Surgeon: C. S. McK. Murison to the *Vivid*, additional, for R.N. Barracks at Devonport.

ROYAL ARMY MEDICAL CORPS.

Captain Douglas S. B. Thomson is placed on the Half-pay List on completion of 10 years' service with the Egyptian Army (dated April 20th).

Lieutenant John F. Hutton relinquishes his temporary commission on account of ill-health (dated March 26th).

Lieutenant John P. Brown relinquishes his temporary commission (dated May 10th).

The undermentioned are granted temporary honorary rank whilst serving with the British Red Cross Society in France:—As Lieutenant-Colonel: Leonard Nicholas Robinson (dated June 6th). As Major: Charles George Jarvis (dated June 6th). Sir David Hardie to be temporary Major (dated April 4th). Captain John Charles Davies, 4th Battalion, The Royal Welsh Fusiliers, Territorial Force, to be temporary Major whilst employed with the Field Ambulances of the 43rd Division (dated May 12th).

Alfred Wills to be temporary Lieutenant whilst serving with the British Red Cross Hospital, Netley (dated June 7th).

The undermentioned to be temporary Majors: Major Robert Thomas Hughes, Welsh Divisional Train, The Army Service Corps (dated May 17th). Major Nathaniel Samuel Manning, 6th Battalion, The Devonshire Regiment (dated May 18th). Major Edward Burdett Pooley, 4th Battalion, The King's Own (Royal Lancaster Regiment) (dated May 19th). Arthur Neve (dated April 8th) and Philip Turner (dated May 18th). Richard Gundry Rows is granted temporarily the honorary rank of Major whilst doing duty at Moss Side Military Hospital (dated May 28th). Elwin Harral Thomas Nash to be temporary Major whilst employed at the Lord Derby War Hospital (dated March 24th).

Attached to Units other than Medical Units.—Surgeon-Major Arthur C. Oldham, from 2nd South Midland Brigade, Royal Field Artillery, to be Major. Captain Arthur C. Bird, from the Territorial Force Reserve, to be Captain. Captain Haldinstein D. Davis is restored to the establishment. Lieutenant Cecil W. Rowntree to be Captain, and to remain seconded. George James Elliot Trotter to be Lieutenant.

Deaths in the Services.

Deputy Surgeon-General Henry Joseph Rose, formerly in the 2nd (Queen's) and West Yorkshire Regiment, at a nursing home in London on June 2nd, aged 82. He joined the Army Medical Service in 1855 and saw service in the Crimea (medal with clasp and Turkish medal). He also took part in the China War of 1860 (medal with two clasps) and in the Afghan War of 1878–80 (medal). He retired in 1881.

Surgeon-General George William Robertson Hay, I.M.S., formerly principal medical officer of the Madras Command, on May 27th, at a nursing home in Edinburgh, aged 70. He retired from active service a few years ago.

Deputy Surgeon-General Christopher Joynt, I.M.S. (retd.), suddenly on June 4th, at the advanced age of 87. Born in Ballina, Co. Mayo, and educated in Queen's College, Galway, within a few years of its opening, he entered the Indian Medical Service and went to India shortly after the Mutiny. He served in the Persian Expeditionary Force in 1857, with the Okamandel and Kattywar Field Forces, 1859–60, and in the Abyssinian Campaign. He was for some time professor of midwifery in Bombay and was principal medical officer of the Quetta District. Since his retirement he has lived in Dublin, devoting himself to philanthropic and religious work. He was greatly interested in the study of theology. He was until recently a constant attendant at the meetings of the Royal College of Physicians of Ireland, of which he was a Fellow. Of late years his sight was failing, but he had unusually good health for a man of his age. Two of his sons are in the medical profession, one practising in Fiji and one in South Africa.

Indian Medical Service Promotions.

Consequent on the suspension during the war of examinations for promotion, lieutenants with less than three years' service will be promoted to the rank of captain on completion of that term of service, irrespective of whether they have passed the prescribed examinations or not, provided they are qualified in all other respects. Lieutenants who have already completed three years' service and who have not passed, or have failed to pass, will be promoted as from Oct. 22nd, 1914, the earliest date on which they could have presented themselves for examination in the ordinary course, provided they are certified to be fit for promotion in all other respects. Lieutenants who have not been able for approved reasons to present themselves for examination will be dealt with under the ordinary rules. Promotions made under these orders, which have been issued by the Government of India, will be regarded as provisional, subject to the officers passing the required examination at the first opportunity on the restoration of normal conditions.

THE ROYAL NAVY LIST.

A second edition of the Royal Navy List, containing a special war supplement bringing the records of men and ships up to date (May, 1915), has just been issued. The alphabetical arrangement of this book, as regards the services of the personnel, greatly facilitates ready reference. A current history of the Royal Navy, the events of the war, and a summary of ships' services and commissions are other useful features of this publication. Messrs. Witherby and Co., 326, High Holborn, London, are the publishers, and the price is 7*s*. 6*d*.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN the 96 English and Welsh towns with populations exceeding 50,000 persons at the last Census, 7337 births and 4756 deaths were registered during the week ended Saturday, May 29th. The annual rate of mortality in these towns, which had been 15·5, 14·2, and 15·4 per 1000 in the three preceding weeks, declined in the week under notice to 13·7 per 1000 of the average population estimated at 18,136,180 persons at the middle of last year. During the first eight weeks of the current quarter the mean annual death-rate in these towns averaged 16·6, against a corresponding rate of 17·1 per 1000 in London. The annual death-rate in the week under review ranged from 4·3 in Lincoln, 5·9 in Bath, 6·0 in Wallasey, 6·4 in Hornsey, and 6·5 in Acton, to 20·9 in Huddersfield, 21·3 in Halifax, 22·1 in Barrow-in-Furness, 22·9 in South Shields, and 24·7 in Middlesbrough.

The 4756 deaths from all causes were 584 fewer than the number in the previous week, and included 439 which were referred to the principal epidemic diseases, against 484 and 603 in the two preceding weeks. Of these 439 deaths, 221 resulted from measles, 90 from whooping-cough, 64 from infantile diarrhœal diseases, 31 from diphtheria, 21 from scarlet fever, 11 from enteric fever, and 1 from small-pox. The mean annual death-rate from these diseases was equal to 1·3, or 0·4 per 1000 less than in the previous week. The deaths attributed to measles, which had been 276, 238, and 309 in the three preceding weeks, fell to 221, and caused the highest annual death-rates of 1·8 in Coventry, 1·9 in Dewsbury, 2·0 in Sunderland, 2·3 in Northampton, 3·0 in West Bromwich, 3·3 in South Shields, 3·4 in Sheffield, 6·1 in Walsall, and 6·6 in Middlesbrough. The deaths referred to whooping-cough, which had been 121, 105, and 137 in the three preceding weeks, declined to 90 in the week under notice, and included 18 in London, 6 each in Liverpool and Wigan, 5 in Birmingham, and 3 in South Shields. The fatal cases of diarrhœa and enteritis (among infants under 2 years), which had been 67, 57, and 70 in the three preceding weeks, fell to 64, of which 13 were registered in London, 5 in Liverpool, and 3 in Barrow-in-Furness. The deaths attributed to diphtheria, which had been 51, 48, and 51 in the three preceding weeks, declined to 31, and included 6 in London and 3 in Birmingham. The deaths referred to scarlet fever, which had declined from 34 to 20 in the four preceding weeks, were 21 in the week under review, of which 4 occurred in London and 2 each in Northampton and Wigan. The fatal cases of enteric fever, which had been 12, 11, and 15 in the three preceding weeks, fell to 11, and included 3 in Manchester and 2 each in Stoke-on-Trent and Liverpool. The death from small-pox was registered in Bristol.

The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, which had been 2384, 2332, and 2286 at the end of the three preceding weeks, further fell to 2252 on May 29th; 257 new cases were admitted during the week, against 307, 270, and 320 in the three preceding weeks. These hospitals also contained on the aforementioned date 1089 cases of diphtheria, 126 of measles, 51 of enteric fever, 11 of whooping-cough, and 1 of small-pox. The 1139 deaths from all causes in London were 149 fewer than in the previous week, and corresponded to an annual death-rate of 13·1 per 1000. The deaths referred to diseases of the respiratory system, which had steadily declined from 469 to 212 in the six preceding weeks, further fell to 182 in the week under notice, but were 17 in excess of the number registered in the corresponding week of last year.

Of the 4756 deaths from all causes in the 96 towns 252 resulted from different forms of violence and 353 were the subject of coroners' inquests, while 1412 occurred in public institutions. The causes of 40, or 0·8 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in Leeds, Bristol, West Ham, Bradford, Hull, and in 72 other smaller towns. Of the 40 uncertified causes of death, 10 were registered in Birmingham, 5 in Liverpool, 3 each in Stoke-on-Trent and Darlington, and 2 each in London, Gillingham, Bootle, and Sheffield.

In the 96 English and Welsh towns 9202 births and 4847 deaths were registered during the week ended Saturday, June 5th. The annual rate of mortality in these towns, which had been 14·2, 15·4, and 13·7 per 1000 in the three preceding weeks, rose in the week under notice to 13·9 per 1000. During the first nine weeks of the current quarter the mean annual death-rate in these towns averaged 16·3, against a corresponding rate of 16·7 per 1000 in the metropolis. The annual death-rate last week ranged from 4·6 in Reading, 6·2 in Walthamstow, 6·4 in Hornsey, 6·6 in Ealing, and 6·8 in Enfield, to 20·8 in Rotherham, 23·7 in Carlisle, 23·9 in Middlesbrough, 27·6 in Sunderland, and 28·2 in Gillingham.

The 4847 deaths from all causes were 91 in excess of the number in the previous week, and included 489 which were referred to the principal epidemic diseases, against 603 and 439 in the two preceding weeks. Of these 489 deaths, 239 resulted from measles, 90 from whooping-cough, 75 from infantile diarrhœal diseases, 50 from diphtheria, 22 from scarlet fever, and 13 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases was equal to 1·4, against 1·3 per 1000 in the previous week. The deaths attributed to measles, which had been 238, 309, and 221 in the three preceding weeks, rose to 239 last week, and caused the highest annual death-rates of 2·1 in Derby, 2·2 in Walsall, 2·6 in Stockton-on-Tees, 3·2 in Barrow-in-Furness, 4·1 in Sunderland, 4·2 in Sheffield, 4·5 in Middlesbrough, and 5·3 in West Bromwich. The deaths referred to whooping-cough, which had been 105, 137, and 90 in the three preceding weeks, were again 90 last week, and included 23 in London, 9 in Liverpool, 4 in Birmingham, and 3 each in East Ham, Manchester, and South Shields. The fatal cases of diarrhœa and enteritis (among infants under 2 years), which had been 57, 70, and 64 in the three preceding weeks, rose to 75 last week, of which 15 occurred in London, 7 in Manchester, 5 in Sheffield, and 4 each in Birmingham and Liverpool. The deaths attributed to diphtheria, which had been 48, 51, and 31 in the three preceding weeks, rose to 50 last week, and included 13 in London, 5 in Northampton, and 3 in Norwich. The deaths referred to scarlet fever, which had been 25, 20, and 21 in the three preceding weeks, were 22 last week, of which 7 were registered in London, and 2 each in Warrington and Manchester. The fatal cases of enteric fever, which had been 11, 15, and 11 in the three preceding weeks, rose to 13 last week, and included 2 each in Bristol and Manchester.

The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, which had declined from 2384 to 2252 in the four preceding weeks, had increased to 2267 on Saturday last; 327 new cases were admitted during the week, against 270, 320, and 257 in the three preceding weeks. These hospitals also contained on Saturday last 1091 cases of diphtheria, 110 of measles, 50 of enteric fever, 11 of whooping-cough, and 1 of small-pox. The 1151 deaths from all causes in London were 12 in excess of the number in the previous week, and corresponded to an annual death-rate of 13·3 per 1000. The deaths referred to diseases of the respiratory system, which had steadily declined from 469 to 182 in the seven preceding weeks, were 181 last week, and were 2 in excess of the number recorded in the corresponding week of last year.

Of the 4847 deaths from all causes in the 96 towns, 227 resulted from different forms of violence, and 344 were the subject of coroners' inquests, while 1468 occurred in public institutions. The causes of 45, or 0·9 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in Manchester, Leeds, Bristol, West Ham, Bradford, Hull, and in 71 other smaller towns. Of the 45 uncertified causes, 8 were registered in Liverpool, 7 in Gillingham, 5 in Birmingham, 4 in Sunderland, 3 each in Warrington and Gateshead, and 2 each in Preston and Barrow-in-Furness.

HEALTH OF SCOTCH TOWNS.

In the 16 largest Scotch towns, with an aggregate population estimated at 2,345,500 persons at the middle of this year, 1075 births and 818 deaths were registered during the week ended Saturday, May 29th. The annual rate of mortality in these towns, which had declined from 20·2 to 16·1 per 1000 in the four preceding weeks, rose to 18·2 per 1000 in the week under notice. During the first eight weeks of the current quarter the mean annual death-rate in these towns averaged 18·8, against a corresponding rate of 16·6 per 1000 in the large English towns.

Among the several towns the death-rate in the week under review ranged from 10·1 in Paisley, 10·2 in Kirkcaldy, and 11·3 in Motherwell, to 20·7 in Leith, 22·1 in Perth, and 23·7 in Aberdeen.

The 818 deaths from all causes were 94 in excess of the number in the previous week, and included 145 which were referred to the principal epidemic diseases, against numbers declining from 150 to 90 in the four preceding weeks. Of these 145 deaths, 72 resulted from measles, 43 from whooping-cough, 15 from infantile diarrhœal diseases, 10 from diphtheria, and 5 from scarlet fever, but not one from enteric fever or from small-pox. The mean annual death-rate from these diseases was equal to 3·2, against a corresponding rate of 1·3 per 1000 in the large English towns. The deaths attributed to measles, which had been 47, 49, and 36 in the three preceding weeks, rose to 72, and included 53 in Glasgow, 13 in Aberdeen, and 4 in Falkirk. The deaths referred to whooping-cough, which had declined from 82 to 40 in the four preceding weeks, rose to 43, and comprised 25 in Glasgow, 5 each in Edinburgh and Aberdeen, 4 in Dundee, 3 in Hamilton, and 1 in Leith. The fatal cases of diarrhœa and enteritis (among infants under 2 years), which had been 15, 9, and 5 in the three preceding weeks, rose to 15, and included 3 each in Glasgow and Dundee, and 2 each in Edinburgh, Aberdeen, and Motherwell. The deaths attributed to diphtheria, which had been 7, 8, and 2 in the three preceding weeks, rose to 10, of which 5 occurred in Glasgow. The 5 fatal cases of scarlet fever included 3 in Glasgow and 2 in Aberdeen, and were 2 below the average in the earlier weeks of the quarter.

The deaths referred to diseases of the respiratory system, which had been 118, 121, and 117 in the three preceding weeks, rose to 141 in the week under notice, and were 45 in excess of the number recorded in the corresponding week of last year. The deaths attributed to violence numbered 26, against 26 and 21 in the two preceding weeks.

In the 16 largest Scotch towns 1171 births and 848 deaths were registered during the week ended Saturday, June 5th. The annual rate of mortality in these towns, which had been 17·9, 16·1, and 18·2 per 1000 in the three preceding weeks, further rose to 18·9 per 1000 in the week under notice. During the first nine weeks of the current quarter the mean annual death-rate in these towns averaged 18·8, against a corresponding rate of 16·3 per 1000 in the large English towns. The annual death-rate last week ranged from 10·9 in Ayr, 11·7 in Leith, and 11·8 in Coatbridge, to 20·9 in Dundee, 21·0 in Glasgow, and 21·8 in Aberdeen.

The 848 deaths from all causes were 30 in excess of the number in the previous week, and included 147 which were referred to the principal epidemic diseases, against 90 and 145 in the two preceding weeks. Of these 147 deaths, 85 resulted from measles, 40 from whooping-cough, 10 from infantile diarrhœal diseases, 7 from scarlet fever, and 5 from diphtheria, but not one from enteric fever or from small-pox. The mean annual death-rate from these diseases was equal to 3·3, against 1·4 per 1000 in the large English towns. The deaths referred to measles, which had been 49, 36, and 72 in the three preceding weeks, further rose to 85 last week, and comprised 70 in Glasgow, 4 in Aberdeen, 3 each in Dundee, Kirkcaldy, and Clydebank, and 2 in Perth. The deaths referred to whooping-cough, which had been 45, 40, and 43 in the three preceding weeks, fell to 40 last week, and included 20 in Glasgow, 5 each in Edinburgh and Dundee, 4 in Aberdeen, and 2 in Kilmarnock. The fatal cases of diarrhœa and enteritis (among infants under 2 years), which had been 9, 5, and 15 in the three preceding weeks, fell to 10 last week, and included 4 each in Glasgow and Dundee. The 7 deaths referred to scarlet fever, of which 3 occurred in Glasgow and 2 in Aberdeen, were equal to the average in the earlier weeks of the quarter. The fatal cases of diphtheria, which had been 8, 2, and 10 in the three preceding weeks, fell to 5 last week, but showed no excess in any of the towns.

The deaths referred to diseases of the respiratory system, which had been 121, 117, and 141 in the three preceding weeks, further rose to 145 in the week under notice, and were 46 in excess of the number in the corresponding week of last year. The deaths attributed to violence numbered 35, against 21 and 26 in the two preceding weeks.

HEALTH OF IRISH TOWNS.

In the 27 town districts of Ireland, with an aggregate population estimated at 1,212,380 persons at the middle of this year, 653 births and 382 deaths were registered during the week ended Saturday, May 29th. The annual rate of mortality in these towns, which had been 19·9, 18·8, and 18·3 per 1000 in the three preceding weeks, further fell to 16·4 per 1000 in the week under notice. During the first eight weeks of the current quarter the mean annual death-rate in these towns averaged 20·1, against corresponding rates of 16·6 and 18·8 per 1000 in the English and Scotch towns respectively. The death-rate in the week under review was equal to 17·0 in Dublin (against 13·1 in London and 19·7 in Glasgow), 16·9 in Belfast, 19·0 in Cork, 16·5 in Londonderry, 17·6 in Limerick, and 7·6 in Waterford, while in the 21 smaller towns the mean death-rate was 14·4 per 1000.

The 382 deaths from all causes were 43 fewer than in the previous week, and included 20 which were referred to the principal epidemic diseases, against numbers declining from 41 to 24 in the five preceding weeks. Of these 20 deaths, 10 resulted from measles, 4 from infantile diarrhœal diseases, 3 from whooping-cough, and 1 each from enteric fever, scarlet fever, and diphtheria, but not one from small-pox. The mean annual death-rate from these diseases was equal to 0·9, against corresponding rates of 1·3 and 3·2 per 1000 in the English and Scotch towns respectively. The deaths attributed to measles, which had been 10, 4, and 9 in the three preceding weeks, were 10 in the week under notice, of which 5 occurred in Belfast and 3 in Dublin. The deaths of infants (under 2 years) referred to diarrhœa and enteritis, which had declined from 10 to 4 in the four preceding weeks, were again 4, and comprised 3 in Belfast and 1 in Wexford. The fatal cases of whooping-cough, which had been 9, 10, and 5 in the three preceding weeks, further fell to 3, of which 2 were registered in Belfast and 1 in Dundalk. The deaths from enteric fever and diphtheria were recorded in Dublin, and that from scarlet fever in Belfast.

The deaths referred to diseases of the respiratory system, which had been 76, 82, and 93 in the three preceding weeks, fell to 63 in the week under notice. Of the 382 deaths from all causes, 120, or 31 per cent., occurred in public institutions, and 9 were attributed to different forms of violence. The causes of 11, or 2·9 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest; in the large English towns the proportion of uncertified causes did not exceed 0·8 per cent.

In the 27 town districts of Ireland 645 births and 396 deaths were registered during the week ended Saturday, June 5th. The annual rate of mortality in these towns, which had declined from 19·9 to 16·4 per 1000 in the four preceding weeks, rose to 17·0 per 1000 in the week under notice. During the first nine weeks of the current quarter the mean annual death-rate in these towns averaged 19·8, against corresponding rates of 16·3 and 18·8 per 1000 in the English and Scotch towns respectively. The annual death-rate last week was equal to 19·0 in Dublin (against 13·3 in London and 21·0 in Glasgow), 16·7 in Belfast, 15·6 in Cork, 20·2 in Londonderry, 23·0 in Limerick, and 15·2 in Waterford, while in the 21 smaller towns the mean death-rate was 13·0 per 1000.

The 396 deaths from all causes were 14 in excess of the number in the previous week, and included 27 which were referred to the principal epidemic diseases, against numbers declining from 41 to 20 in the six preceding weeks. Of these 27 deaths, 12 resulted from infantile diarrhœal diseases, 5 each from scarlet fever and whooping-cough, 3 from measles, and 2 from diphtheria, but not one from enteric fever or from small-pox. The mean annual death-rate from these diseases was equal to 1·2, against corresponding rates of 1·4 and 3·3 per 1000 in the English and Scotch towns respectively. The deaths of infants (under 2 years) from diarrhœa and enteritis, which had declined from 10 to 4 in the five preceding weeks, rose to 12 last week, and comprised 8 in Dublin, 3 in Belfast, and 1 in Cork. The 5 deaths referred to scarlet fever were 3 in excess of the average in the earlier weeks of the quarter, but showed no excess in any particular town. The fatal cases of whooping-cough, which had been 10, 5, and 3 in the three preceding weks, rose to 5 last week, of which 3 occurred in Dublin. The deaths attributed to measles, which had been 4, 9, and 10 in the three preceding weeks, fell to 3 last week, and included 2 in Dublin and 1 in Belfast. The fatal cases of diphtheria were recorded in Dublin and Belfast.

The deaths referred to diseases of the respiratory system, which had been 82, 93, and 63 in the three preceding weeks, fell to 56 in the week under notice. Of the 396 deaths from all causes, 128, or 33 per cent., occurred in public institutions, and 12 resulted from different forms of violence. The causes of 12, or 3·0 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest; in the 96 English towns the proportion of uncertified causes did not exceed 0·9 per cent.

THE death is announced of Dr. Alfred Hollis of Freshwater, Isle of Wight. Dr. Hollis qualified in 1867 as L.S.A., taking the M.R.C.S. in 1868, the M.B., C.M. of Edinburgh in 1869, and proceeding to the M.D. degree of that university in 1873. He had been civil surgeon in charge of the Royal Engineers at Fort Victoria, and medical officer of health of Yarmouth, Isle of Wight. He was a friend of Tennyson, and one of his medical attendants.

Correspondence.

"Audi alteram partem."

THE METROPOLITAN HOSPITAL SUNDAY FUND: THE APPEAL OF THE LORD MAYOR OF LONDON.

To the Editor of THE LANCET.

SIR,—May I, as president and treasurer of the Metropolitan Hospital Sunday Fund, remind your readers that on Sunday next, June 13th, they have their annual opportunity of showing practical sympathy with the work of our London hospitals.

This year the need is greater and the call clearer than ever, for, in addition to the ordinary work of healing the sick poor, the hospitals have nursed and cared for many thousands of our brave sailors and soldiers, and the doctors and nurses now at "the front" would readily tell how much of their knowledge they owe to hospital training in London.

Every man restored fills a gap in the line; every contribution, therefore, is a help towards victory.

I will gladly receive and acknowledge any sums sent to me by those who cannot be at their place of worship next Sunday.

I am, Sir, your obedient servant,
CHARLES JOHNSTON,
Lord Mayor.

The Mansion House, London, E.C., June 10th, 1915.

As chairmen respectively of the Committees of Distribution, General Purposes, and Finance we warmly support the Lord Mayor's appeal.

(Signed) A. S. CHURCH,
DAVID ANDERSON,
C. ERNEST TRITTON.

THE WAR AND THE SUPPLY OF MEDICAL OFFICERS.

To the Editor of THE LANCET.

SIR,—I was glad to see that in the leading article of your issue of June 5th you have taken up the question of the supply of medical officers in connexion with the war. The experience gained so far by the War Emergency Committee of the Metropolitan Counties Branch of the British Medical Association shows very definitely enormous difficulties in the way, and much might be written on the curious anomalies which have come to the notice of the committee. But the essential question is to prepare a scheme for what you rightly describe as the "mobilisation of the whole profession."

There are only three ways in which the supply of medical officers for the army can be made good: (1) by voluntary recruiting; (2) by compulsory service; (3) by the importation of foreigners.

Compulsory service is probably the most satisfactory solution; but conscription is a political question at present, and however likely it may seem in the future, it must not be counted upon at present. The importation of foreigners would not only cast a slur on the British profession, but might also very well lead to unsatisfactory conditions when the Royal Army Medical Corps officer comes to work side by side with the foreigner at the front.

Can voluntary recruiting satisfy the requirements? To my mind it can, but only under certain conditions, of which the first and most important is that all the different bodies concerned in war service should be in touch with one another. The medical authorities of the War Department are supreme in dealing with officers actually in the army; but they cannot know anything about civilian practice. Therefore they must be in close touch with a body representative of every side of medical practice. Such a representative body should include hospital men, general practitioners, officials of societies such as the Red Cross, and a layman or so to voice the sentiments of the patriotic philanthropist who has placed private hospitals and other such facilities at the disposal of the Government. This body needs a central office and clerical assistance in order that records may be kept. Every medical man should be recorded, with his age and the service for which he is suitable. Every hospital should be noted with its staff and the number of medical men required for its working. When fresh men are required for any service the War Department should communicate with this office, whereupon a list of suitable names would be submitted, from which the war authorities would select the number of men they require. In this way overlapping, over-work, and the over-staffing of hospitals, especially with men of unsuitable age, might be avoided.

To get anywhere near an ideal arrangement of this kind two things are necessary, both in individuals and in bodies of men—(1) the avoidance of jealousy; and (2) the recognition of one's limitations. Much of the difficulty of the present situation is due to jealousy between different bodies, and between individual men. The lack of recognition of one's limitations is shown at the War Office by the attempt to deal in an unorganised way with a body of civilian practitioners of which the department knows nothing; it is shown by the civilian practitioners in attempting to dictate conditions in a matter on which they are ignorant—the organisation of the R.A.M.C.; by the military and civil hospitals, and by the Red Cross Society, which are run without any coördination or settled line of action with regard to their junior staffs and other points.

To me it appears that none of these troubles can be adjusted except through a central bureau, clearing house, exchange, or whatever it may be called. To form such a body and to have it accepted, recognised, and used by the War Department and by everyone interested in the successful organisation of the medical profession, is the idea I suggest; and if ever the suggestion is adopted I would implore all parties to forget their petty jealousies, to recognise their individual limitations, and to work in a united manner for the achievement of success.

I am, Sir, yours faithfully,

Inverness-terrace, W., June 7th, 1915. CHAS. BUTTAR.

THE EFFECT OF ATROPINE IN "GASSED" PATIENTS.

To the Editor of THE LANCET.

SIR,—I was glad to read Dr. Ida C. Tengely's letter on this subject in your issue of June 5th, in that her experiences afford a certain confirmation of the suggestion that atropine is beneficial to those suffering from the effects of irritant gases.

I should like to criticise, if I may, her suggestion for using atropine as a prophylactic measure against such gases. Surely the "tightness of the chest" or bronchial spasm produced by such irritants is Nature's way of attempting to lessen the amount of these gases inhaled, and consequently to reduce to a minimum the damage to the respiratory apparatus. It follows that the administration of atropine prior to exposure to such gases, by paralysing the broncho-dilator nerve endings, would effectually prevent the slightest degree of broncho-constriction; in other words, a widely dilated air-passage would be ready to receive large inhalations of the irritant fumes. Consequently the damage to the respiratory apparatus would be likely to be increased.

On the contrary, *after* the irritant gases have been inhaled, the air passages being full of an inflammatory exudate and a certain degree of bronchial spasm being present, the subject experiences a "tightness of the chest"—a difficulty in forcing air into the lungs, and probably a still greater difficulty in expelling the CO_2 from the lungs. By relieving the spasm and opening out the air passages to their widest possible calibre atropine is of the greatest value in relieving the distressing and exhausting symptoms.

May I add the fervent hope that if Dr. Tengely has the misfortune to be in the proximity of a 'gas cloud," she will for her own sake keep her dose of atropine until the cloud has passed.

I am, Sir, yours faithfully,
DOUGLAS COW.

Pharmacological Laboratory, Cambridge, June 7th, 1915.

THE MANAGEMENT AND TREATMENT OF YAWS EXEMPLIFIED BY TWO CASES.

To the Editor of THE LANCET.

SIR,—The usual method, as far as I know, of dealing with yaws cases in the tropics in the British West Indies is more or less similar in every one of the islands. There is a faithful similarity among the management and reports that savours strongly of a slavish attachment to red-tapeism and an utter lack of originality. Segregation is the chief object desired, and ordinances are passed from time to time to drive yaws-infected patients to special hospitals, where they reside from three months to three years under treatment, while some are quite satisfied to make the hospital their permanent homes. I cannot say that I have seen anywhere in the British West Indies signs of any vigorous and scientific interest in the management of yaws-infected persons. There have been from time to time spasmodic revivals of interest taken in the disease, but soon to subside into the humdrum routine and indifference that is characteristic of everything West Indian. I have known a case of yaws return from the hospital after a year's residence showing well-marked nodules. It is with a view, if possible, to revive an active interest in this disease that I venture on the publication of this protest, for I feel sure that working on right lines the stamping out of yaws is a measure not only possible but extremely probable. It has already been noted that the prevalency of yaws in the British West Indies is on the decrease, but nobody, I think, has given a thought to the proper reason for this happy result. It has not been brought about by the efforts of the different governments, which if anything are a drawback to its ultimate eradication, nor has it been effected by the successful scientific treatment of yaws cases admitted yearly in the hospitals instituted for that purpose. Those who know and have watched the progress of these West Indian Islands cannot have failed to observe the simultaneous advance of scientific agriculture and the gradual decrease of the disease known as yaws. There is no room to doubt that from the moment that agriculture took on a rational and scientific turn there was an appreciable decrease in the incidence of the disease. This is remarkably exemplified in the small island of Grenada, where the brush has been applied to some advantage. The squatters attached to estates in that island, who lived anyhow and whose wages of 1*s.* a day were hardly sufficient to maintain the ordinary needs of life, were removed, and agriculture was pushed on a scientific and business-like manner, and almost immediately the prevalency of yaws declined. Grenada is now, I believe, ready to apply the remedy to a section of her population by reclaiming estate lands wherewith to dump her surplus population in a fresh and cleanly made peasantry. In that island the authorities take some interest in the poorer section of the people.

With regard to the treatment of yaws, the system of routine has even been more marked. Since the advent of the spirochætæ the contagiousness of yaws seems to have been adopted universally as an admitted fact, yet, in my humble opinion, there has never been a greater mistake made. Syphilis is constantly being confounded with yaws, which I venture to think is purely and simply a non-contagious skin disease. There is no difficulty in demonstrating the spirochæta pallida of syphilis, and it does not require an expert to do that. I have repeatedly done so, and showed it to intelligent people who took an interest in such matters, yet not once have I been able to obtain the organism of yaws. I cannot see why the one should be more difficult to obtain than the other under the ordinary methods prescribed. The virtues of arsenical preparations as the specific treatment in yaws are not new, and I, years ago, strongly suggested it as the only drug which can be depended upon for a speedy cure of the disease. The coming of salvarsan as a specific treatment in yaws is somewhat of a misfortune, if only for this reason, that the drug has been used too indiscriminately and without technical knowledge on the part of the operators. A second reason is that a very much less dangerous preparation of arsenic, intelligently used, can have the same effect, without endangering the life of the patient. The wholesale injection of salvarsan for the cure of yaws in incompetent hands cannot be too strongly deprecated, while the routine habit of injecting every patient on admission, whether able to bear the remote effects of such a powerful remedy or not, is extremely dangerous. A couple of cases which have come under my notice would suffice to show the carelessness evinced in the use of salvarsan in the routine treatment of yaws.

CASE 1.—A girl aged 17 to 18 years, the only help to poor and hardworking parents. She contracted yaws and was by the ordinance forced to go to a yaws hospital, where she received two injections of "606." On her return from the hospital, apparently in good health, she returned to her gardening. On the sixth day of her return home she was taken with chills, fever, and "bursting" headache. She appeared to be drowsy or dozed, her tongue was protruded slowly and with difficulty, and she could not, or would not, answer questions. I procured two ounces of her urine by catheterisation. I ordered her an immediate hot bath, to be followed by grain doses of calomel and soda every hour for six hours. I found the sample of urine to be highly albuminous, and there seemed no doubt as to the diagnosis. About 6 P.M. on the same day I found her comatose, having, just before my arrival, had severe convulsions. I then opened the right median basilic vein and let out five ounces of blood, but to no purpose; she died during the night. There was no reason to suppose that the girl showed any signs of kidney disease before her sojourn in the hospital, but that she succumbed to acute uræmia following upon almost complete suppression of urine there can be no room for doubt. I have not the least doubt that the injection of salvarsan received constituted the chief cause of her kidney trouble and her death.

CASE 2.—A little girl, aged 5 years, who had had crabs in the sole of her left foot for two years. She was sent to the yaws hospital where she received an injection of "606" on admission. The site of the puncture was in the left buttock and immediately over the course of the great sciatic nerve. She came to me eight months after the injection for fever and an enlarged spleen, but noticing that she dragged her left leg and had a peculiar gait, I got from the mother the history of the treatment at the yaws hospital. When she left the yaws hospital her left leg was dragging and painful, and there was a lump of about the size of a small Tangerine orange at the site of the puncture. Her mother, observing a small aperture at the top of the swelling, squeezed, and suddenly there spurted out about a teaspoonful or more of matter. The swelling subsided gradually but the left leg and foot remained weak, and she has never been able to regain her proper gait since the operation, it being now over eight months. Here, then, is a child, crippled for life by the inadvertency of a careless operator. What has occurred is fairly obvious, and the damaged nerve is likely to be a source of trouble for the balance of this child's life.

I venture to think that if all the cases of yaws treated with salvarsan were to be systematically examined the statistics of failures would be found to be far greater than the average of successes published in the reports, or the calamities attendant on its use would be so alarming as to demand an immediate check on the indiscriminate use of such a powerful remedy.

I am, Sir, yours faithfully,

Port of Spain, Trinidad, B.W.I. A. B. DUPREY.

ELECTRIC TREATMENT IN ARTERIO-SCLEROSIS.

To the Editor of THE LANCET.

SIR,—With reference to your abstract of a very able article on arterio-sclerosis by Dr. W. Lyne Blight in THE LANCET of June 5th, in the paragraph which treats of the treatment of this condition there is no mention made of the value of electric current. It is generally conceded by those who have any knowledge of electricity as a therapeutic agent that it has the power of modifying pathological arterial tension. The headache, which is present when the sclerosis affects the cerebral vessels, can usually be instantly relieved by the proper application of electricity, and there occurs coincidentally with this a fall in the pressure as registered by the sphygmomanometer. Very often the instrument will register a drop of 20 millimetres in 15 minutes with the patient feeling more cheerful and in better temper. At the same time there is evidence of increased oxidation, the output of the urea is increased, and that of uric acid diminished—that is to say, nitrogenous matter becomes more completely oxidised.

Of the various modalities the current of D'Arsonval is the most efficacious. The manner in which it is applied varies with the operator, some, especially the French physicians, preferring the auto-condensation cage, whereas in America the auto-condensation couch is more general; both give equally good results, provided that a current of sufficient ampèrage be employed, say, 1000 milliampères, which is not difficult, provided that the coil and condensers are of sufficient capacity and a multiple spark-gap be put in circuit. The current may be passed for 10 to 15 minutes, or until the patient flushes or the skin becomes moist. The treatment should be given daily, or thrice weekly, according to the nature of the case and the readiness or otherwise with which the patient responds to the treatment. Frequent reading of the sphygmomanometer should be taken as a guide to the treatment. Headache and a feeling of lassitude are sometimes noted after one or two treatments. These are due to the fact that in consequence of the rapid tissue change induced by the treatment more toxins are liberated than can be carried off. These facts will be more marked should constipation be present and altogether avoided if the bowels are kept freely opened.

I have been using this method for over 10 years and can confidently speak to its beneficial effects, and feel that no monograph or article dealing in arterio-sclerosis or a raised arterial tension is complete without a reference to it.

I am, Sir, yours faithfully,

F. HOWARD HUMPHRIS, M.D.

West Chapel-street, Mayfair, W., June 8th, 1915.

PRODUCTION OF LACERATED WOUNDS BY POINTED RIFLE BULLETS.

To the Editor of THE LANCET.

SIR,—The essential factor which normally prevents a rifle bullet turning over in its flight in the air and during its passage through the denser semi-fluid tissues of the body is that it has a certain rate of spin which bears a definite relationship to the forward velocity. This rate of spin depends, of course, on the number of turns which the grooves of the rifling make in the barrel. If this rate of spin is greatly too fast or too slow for the forward velocity, then the bullet will wobble in its flight and eventually turn over, thus producing a lacerated wound. Now the forward velocity of a bullet diminishes very rapidly owing to the resistance of the air to its flight, but the rate of spin is diminished hardly at all, since as the bullet has a smooth surface it meets with hardly any air resistance, and there being therefore almost nothing to slow it, it naturally keeps on spinning at practically its original rate. To give an instance. It is well known that carefully balanced tops have been constructed which will spin for over half an hour, whereas the bullet has only got to maintain its rate of spin for, at most, a few seconds. The result is that the relationship between the rate of spin and the forward velocity is upset, the former becoming too great proportionately for the latter, and the bullet then has a tendency to turn over and thus produce a lacerated wound.

A bullet which makes a clean entrance wound may produce laceration inside the body both for the above reason and also for another—namely, that a rate of spin which correctly corresponds to the forward velocity in the air may be quite incorrect in the denser semi-fluid medium of the body. This explains also the remarkable changes of direction of track of the bullet in the body, which may occur sometimes even apart from striking a hard structure. Generally speaking the blunter a bullet is, the less tendency has it to turn over in its flight either in the air or in the body—that is to say, the more pointed a bullet is the more closely has its rate of spin got to approximate to that which is absolutely correct in order to keep it steady and point foremost during its flight as well in the air as in other media such as the body. This explains the much greater frequency with which the pointed bullet is found to have turned over and thus produced lacerated wounds, than was the case with the old round-nosed bullet.

I am, Sir, yours faithfully,
FRANCIS H. KELLY, M.B., B.S.,
Resident Medical Officer, King George Hospital.
June 1st, 1915.

THE TREATMENT OF GAS POISONING.

To the Editor of THE LANCET.

SIR,—When the effects of asphyxiating gas on our soldiers were first reported I suggested to an eminent surgeon at the front the use of oxygen by subcutaneous injection for those with much obstruction in the respiratory passages. He was so good as to send a reply as follows: "We have tried oxygen subcutaneously in several cases as you propose. It has seemed to be useful and we shall continue to try it, for it is right to try everything one possibly can."

As we may, from bomb-dropping, have to deal with similar conditions in this country, I hope the method may be borne in mind. It has been used for some years in France and Canada[1] in many forms of dyspnœa, including those in which inhalation is impeded mechanically. The technique is simple, all that is needed being a cylinder of oxygen, a piece of rubber tubing, and a hypodermic or small aspirating needle. If the tube is not clean a little wool or gauze might be put as a filter into the end near the needle. The disconnected needle is inserted anywhere into loose subcutaneous tissue —e.g., in the flank. If it have entered a vein, as shown by blood issuing, it should be taken out and inserted elsewhere. Oxygen is turned on at low pressure and the cylinder joined up to the needle. When a swelling such as would be produced by 300 c.c. (10 fl. oz.) of normal saline has slowly appeared the proceeding is repeated in another place, the first swelling being gently massaged to aid diffusion. 1·5 litre (say 54 oz.) has been injected altogether and repeated twice in the same day. It is, however, not necessary to measure the amount. No ill-effects have been recorded, nor even inconvenience, whilst in many cases immediate and considerable relief is stated to have occurred.

I am, Sir, yours faithfully,
J. D. MORTIMER, M.B., F.R.C.S.,
Anæsthetist, Royal Waterloo Hospital, &c.
St. John's Wood, N.W., June 3rd, 1915.

MILITARY HONOURS.

To the Editor of THE LANCET.

SIR,—Ignorant alike of the legal position of those important gentlemen called coroners, in respect to soldiers who die in England from wounds received in France, and of military etiquette with regard to the funerals of such victims, I shall be grateful for information upon the various points which I raise.

A soldier, wounded near Ypres, was admitted into the French Hospital, London, where beds have been placed at the disposal of the War Office. Shortly after admission he developed tetanus, from which, in spite of all that we could do, he died. The registrar refused to certify the death without the coroner's approval, and this was, I understand, only obtained after much time, criticism, and correspondence; but before reaching, with apparent reluctance, the happy conclusion that no inquest was necessary, he telegraphed to the only relation the unfortunate man possessed, a sister, a young girl aged 16, in service in Bath, asking if she was satisfied with the treatment received by her brother while in the hospital, a form of "compliment" which the staff of the hospital, who did everything in their power for the patient, properly appreciated.

Owing to the attitude of the coroner there was considerable delay in arranging the details of the man's funeral. At last, all being in order, nearly a week after his decease, a hearse, a corporal, and some twelve soldiers, arrived to take him away. No Union Jack was provided, but the hospital authorities were able to remedy this omission. On arriving at Kensal Green, however, no arrangements had been made for the services of a clergyman, and it was not until three-quarters of an hour had elapsed that the unfortunate man's remains were buried—without "military honours" in the true sense. All the wounded soldiers in the hospital were aware of these omissions—if omissions they were—and their comments were various and free.

It would be interesting to know whether other coroners practise similar proceedings and pay such delicate compliments to other hospitals, and whether these are the usual arrangements approved of by the War Office. Surely it would be possible for the War Office, the coroner, and the hospital authorities to work in conjunction with one another, so that such a state of things could not occur again.

I am, Sir, yours faithfully,
W. H. CLAYTON-GREENE,
Surgeon to the French Hospital.
June 5th, 1915.

THE PULSUS ALTERNANS.

To the Editor of THE LANCET.

SIR,—In THE LANCET of May 29th Dr. C. O. Hawthorne relates a case in which the pulsus alternans has been present on and off for five years without the manifestation of serious cardiac symptoms. The sphygmogram (Fig. 6) illustrating this case I believe answers Sir James Goodhart's question in your present issue, "When is a pulsus alternans not a pulsus alternans, so far as its now accepted gravity of prognosis goes?"

When interpreting tracings such as this it is important to remember that the respiratory muscles attached to the arm move the arm slightly during breathing if it is at all laboured. Unless the arm is kept still by grasping the condyles while the pulse is recorded, and particularly if the wrist apparatus of the sphygmograph is not securely fixed up, the movements of the arm modify the force of impact between the spring and button of the tambour, and thus cause variations in amplitude of the pulse-curves which are often mistakenly ascribed to changes in blood pressure. For example, if there are three pulses to one breath an apparent pulsus alternans may be occasioned, and with higher ratios the grouping of stronger and weaker beats may be such that one or two low beats alternate with two or three high beats. I have a number of tracings illustrating these fallacies, and the seeming alternation in Fig. 6 of Dr. Hawthorne's paper impresses me as being caused in this way. The outline of the curve, as a whole, suggests laboured breathing with a ratio of three pulses to each breath, and the weaker pulse of the groups of three occurs at the height of inspiration. Further, although the tracing is a close likeness, it is not a true picture of the pulsus alternans; one feature is alien—namely, the length of the downstroke of the weaker beat which equals the length of the downstroke of the stronger beat. In descriptions of the pulsus alternans hitherto given no mention is made of the relative length of the downstroke of the beats. To determine this relationship I have examined a large number of tracings, and I find in true pulsus alternans that although the downstroke of the weaker beat may be longer than its upstroke, it is never so long as the downstroke of the stronger beat. On these considerations I submit, with all deference, that the presence of true pulsus alternans in Fig. 6 cannot be accepted without demur.

---

[1] See THE LANCET, June 22nd, 1912, p. 1726 (Anoxyhæmia of Altitude); Medical Press and Circular, May 1st, 1912, and Dec. 23rd, 1914; also Practitioner, July, 1911, p. 130.

With regard to the prognostic significance of pulsus alternans this has not been worked out, so far as I know, except in one group of cases—namely, when it occurs in association with myocardial and arterial disease in aged people. I published notes of a number of these cases in the *Quarterly Journal of Medicine*, July, 1913, and at that time ten of the patients were living; since, all except one have died, and none of the lot lived much over three years. In other conditions in which the pulsus alternans occurs present experience only warrants this conclusion, that it adds to the gravity of the outlook.

In my own experience it is not met with in rheumatic heart disease, or acute illnesses in the absence of other signs of danger.

I am, Sir, yours faithfully,

June 5th, 1915. J. DAVENPORT WINDLE.

THE GRATUITOUS TREATMENT OF DEPENDENTS.

To the Editor of THE LANCET.

SIR,—I think it is time, if conscription is approaching, for the profession to reconsider their attitude towards the wives and children of those men who are serving either at the front or training in Britain. The number is increasing daily, and is likely to go on doing so. At the present time we are not paid for the insured among these men—a considerable loss to those with a large panel list—and we appear to be in danger of having our practices still further decreased by a large increase in the number of "dependents."

There is no lack of loyalty in the writer of this letter; he has done his share so far, but the future has to be borne in mind. Loyalty will not feed the doctor and educate his family. There is no wish to pile extra burdens on those whose men are fighting for us, so surely this is a matter for Government to arrange.

I am, Sir, yours faithfully,

May 31st, 1915. M.D.

THE USE OF TRAINED NURSES FOR ORDINARY DUTIES.

To the Editor of THE LANCET.

SIR,—I have before me letters from two trained nurses at present serving in stationary hospitals with the Expeditionary Force. One takes spells of duty as cook and housekeeper, while the other has to cook her own meals and wash up afterwards. Both are thoroughly good nurses and both, I believe, are thoroughly bad cooks. I bring the matter forward in the hope that the authorities may be able to prevent such an apparently unnecessary waste of our nursing material. Trained nurses are scarce, but there are many experienced housekeepers, and the women of France have a deservedly high reputation as cooks.

I am, Sir, yours faithfully,

June 4th, 1915. H. B.

THE MEDICAL PROFESSION AND THE NEEDS OF THE ARMY.

To the Editor of THE LANCET.

SIR,—The doubtful manner in which the records of our naval and military successes, no less than of our failures, have reached us—the hesitation as to the real significance of any news vouchsafed—has been as bad almost as silence. Just as in general affairs it makes for good if as much information as is possible, having regard always to the military and political exigencies of the campaign, were published in clear language, so the medical man would be helped by definite information. No one knows better than he how seriously anxiety that is perhaps not justifiable, and puzzledom that need not exist, militate against the output of good work. As a whole we are an educated people, and the desire to understand before we act has increased among us. The feeling is there, and though its manifestations are sometimes inconvenient, it should not be ignored, for that only leads to its aggravation. The output of the munitions of war is stated to have been delayed and even now to be jeopardised by alcoholic habits in certain centres. The statement, while reiterated by some and flatly contradicted by others, has a basis of fact which we should think by this time has been exposed sufficiently to the nation. But the position might have been made clear sooner, when much ill-will would have been avoided, and possibly ready remedies for some of the evil would have been found already.

It seems still to be in doubt how far most stringent calls are yet to be made on the medical profession, and no definite guidance is given to the medical profession as to how such calls should be met. I am, Sir, yours faithfully,

SENEX.

SCIENCE IN CATALONIA.

To the Editor of THE LANCET.

SIR,—The book noticed last week under this heading may be taken to prove the vitality of the revival of the Catalan language, and we should all wish the revival success.

For small states and small nationalities have a precarious existence to look forward to, should the centralisation and unification of nations and countries so vigorously prosecuted by Germany gain any general adoption in Europe. The principle of nationality for which Germany stands is entirely averse from the employment of their native tongues or dialects by subject races, thus contrasting with the principle of encouraging national individuality practised by ourselves. At no period of her history has Spain produced many men of science of European reputation, a fact in striking contrast to her centuries of eminence in the fields of literature and art. Catalonia certainly gave birth to an alchemist of note in the thirteenth century—namely, Raymond Lully—if, indeed, it be not the case that the alchemical writings ascribed to him are forgeries of the fourteenth and fifteenth centuries. The present revival of the Catalan tongue undoubtedly gives an admirable opportunity for the revival of the study of science in Catalonia. May the opportunity be seized! I am, Sir, yours faithfully,

HISPANICUS.

THE BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND.

The Central Committee.

A meeting of the Central Committee was held on Thursday, June 3rd, when the members were put into possession of full details as to the distribution of relief to medical men, pharmacists, and their families and dependents in Belgium. This distribution takes place through the medium of the Aide et Protection aux Médecins et Pharmaciens Belges Sinistrés, extracts from whose recent official reports were published in The Lancet last week. The Belgian Committee works in this way. A strongly constituted central committee sitting in Brussels has appointed a subcommittee for eleemosynary purposes, and to this subcommittee inspectors report on the merits of the individual cases which have come under their ken in particular districts, and make recommendations as to what grants should be given. Papers are filled up for the information of the subcommittee, and the grants are made on the recommendations of the subcommittee, who are stated, on the whole, to have been less stringent than the actual inspectors. Examples of the kind of cases that have been succoured were published in The Lancet last week, and to these the following four cases may be added:—

Dr. C—— L——, of T——, is married, and has one dependent son. His money is exhausted, his premises are completely burnt, he has no means of daily subsistence, and an elder son with whom he hoped to shelter is now a refugee. A grant was made of 700 francs.

Dr. L——, of V——, has two dependent children, his house and all the contents have been burnt, and his economies are exhausted. A grant was made of 700 francs.

Dr. C——, of L——, has also two dependent children. His house and all the contents have been destroyed, and two other houses belonging to him have been burnt. His *clientèle* is ruined and dispersed. He still has some savings. A grant was made of 400 francs.

Madame G——, of A——, saw her husband and one son killed in front of her, and her house was pillaged. One son aged 15 remains. The returns of her late husband's pharmacy have become very small indeed. A grant was made of 700 francs.

At the séance of the Belgian Committee on April 29th an important departure was made, as it was agreed that monthly grants should be given to families of medical men and pharmacists in want. It was pointed out that it would be of great advantage to those who were helped if they had more security and had not always to renew their applications in the face of complete want. As a result it was agreed by the Aide et Protection aux Médecins et Pharmaciens Belges Sinistrés that allowances should be paid in suitable cases of from 300 francs to 600 francs per quarter. Already the distribution of three monthly allowances is being made to families of pharmacists. Complete accounts were furnished to the British Committee by the detailed reports of the proceedings at the séance of April 29th and the two previous sessions, so that it was possible to judge of two things: first, that the resources had been very closely husbanded; and, secondly, that more money is wanted, especially in view of the system of tri-monthly grants. Sir Rickman Godlee, the chairman of the British Fund, and Dr. Des Vœux, the treasurer, were accordingly authorised to send out a substantial sum of money to Belgium through the medium of Mr. Herbert Hoover, the chairman of the International Relief Fund. The cheque is being accompanied by a letter from the chairman of the British Central Committee, to Dr. Péchère, the chairman of the Aide et Protection aux Médecins et Pharmaciens Belges Sinistrés, pointing out that the British Committee cannot undertake to send the same amount monthly or even at stated intervals, but that the amount sent must depend partly on the funds at the disposal of the British Committee and partly upon the actual necessities of the time. In this letter the approval of the British Committee is also expressed of the way in which the relief of distressed doctors and pharmacists and their families has been undertaken by Dr. Péchère's committee.

The Week's Subscriptions.

The subscriptions received by Dr. Des Vœux up to Tuesday evening last, in addition to those previously acknowledged, are as follows:—

	£	s.	d.
Hampstead Division, B M.A. (per Dr. Coode Adams, Chairman and Sec.)	21	0	0
Dumfries and Galloway Division, B.M.A. (per Dr. J. Dewar Robson, Hon. Sec.)—			
Dr. R. B. Lorraine ...	1	1	0
Mrs. R. B. Lorraine ...	1	1	0
Dr. Cowan	0	10	6
Dr. Robson (supplementary)	0	9	9
Dr. W. Bramley Taylor	2	2	0
Brussels Medical Graduates Asso. (per Dr. Major Greenwood, Treas.) (eighth donation—total, £127 15*s.* 6*d.*)	1	1	0
Greenwich and Deptford Division, B.M.A. (per Dr. C. G. Wallis, Hon. Sec.) (second donation—total, £45 8*s.* 6*d.*)—			
Dr. Allan Massey ...	0	10	0
Dr. A. Whitehead ...	0	5	0
Mr. F. A. Williamson (from weighing machine)	0	6	6
Mr. A. Peake	2	12	9
Mr. J. W. Reed (per British Drug Houses, Ltd.)	2	2	0
Mr. John Cooper	0	10	6
Northamptonshire Division, B.M.A. (per Dr. Baxter, Hon. Sec.)—			
Dr. A. W. Cooke... ...	1	1	0
North of England Branch of Fund (per Dr. James Don and Mr. A. S. Perceval, Hon. Secs.) (thirteenth donation, total £709 15*s.* 6*d.*)—			
Dr. E. Gofton	1	1	0
Dr. J. R. Mitchell ...	1	1	0
Dr. C. Franks	1	1	0
Dr. W. Misselwhite ...	2	2	0
Dr. W. W. Stainthorpe	0	10	6
Dr. F. T. Hare	1	1	0
Dr. J. Danholm	1	1	0
Dr. J. Malcolm Shaw	4	0	0
Dr. J. W. Weir	1	1	0
Dr. W. H. Bishop ...	2	2	0
Dr. W. J. Phillips ...	1	1	0
Dr. F. F. Foster	2	2	0
Dr. G. R. Fortune ...	1	1	0
Dr. Craigie Gray ...	1	1	0
Dr. A. Pain	1	1	0
Dr. G. H. Harbottle ...	1	1	0
Dr. W. Horsfield ...	1	1	0

Subscriptions to the Fund should be sent to the treasurer of the Fund, Dr. H. A. Des Vœux, at 14, Buckingham-gate, London, S.W., and should be made payable to the Belgian Doctors' and Pharmacists' Relief Fund, crossed Lloyds Bank, Ltd.

The Appeal for Surgical Instruments.

The Master of the Society of Apothecaries begs to acknowledge the receipt of surgical instruments kindly contributed by the following donors since the publication of the last list:—

Mr. T. P. Beddoes, Welbeck-street, W.; Mrs. W. J. C. Johnstone. Weybridge; Mr. F. W. Smallwood, Handsworth; and Mrs. E. G. Roberts, Uxbridge.

Instruments should be sent to the Apothecaries' Hall, Blackfriars, E.C.

Centenarians.—Mr. John Mitchell, a Crimean veteran, has died at Navan, county Meath, in his 108th year. —The death has been reported in the borough of Stepney of a person aged 102.

Clean Milk Society.—The council of this society are preparing plans for an "infants' welfare" station in one of the poorest quarters of London, where clean milk can be sold to the poor and where mothers can be educated in the care of their young children, on similar lines to the work done in New York. The work of the society will embrace efforts to improve conditions at dairy farms, in railway transportation, and at milk shops, as well as the methods of distribution to consumers' houses and the care of milk in the home.

The War.

THE CASUALTY LIST.

THE names of the following medical officers have appeared in the casualty lists since our last issue:—

Wounded: Surgeon D. D. Pinnock, R.N. (Armoured Car Division), Captain K. B. MacGlashaw, Lieutenant J. T. Heffernan, Lieutenant J. S. Ward, Lieutenant R. O'Kelly, all of the R.A.M.C.; Captain J. J. Black, Australian Medical Corps; Temporary Surgeon J. R. Kay-Mouat, R.N.V.R., Home Battalion.

Missing: Lieutenant J. A. Gillespie, R.A.M.C. (attached 2nd Northumberland Fusiliers).

DEATHS AMONG THE SONS OF MEDICAL MEN.

The following name must be added to the sons of medical men who have fallen in the war: Lieutenant R. W. C. Edginton, only son of Dr. R. W. Edginton, of Edgbaston, Birmingham.

THE MOBILISATION OF THE MEDICAL PROFESSION.

The continuous increase in the number of medical men engaged with the fighting forces, which, whether voluntarily or by compulsion, will sooner or later have to be augmented to a degree greatly beyond anything that has yet been done, coupled with the considerable casualties sustained by the medical services, must inevitably drain the medical reserves of the country and deplete the ranks of the civil medical profession. Indeed, these results have already ensued to a considerable degree. But the making of doctors cannot be expedited as can the making of munitions, because no two or more processes in the moulding of the raw material can be carried out simultaneously. While 50 operatives could undoubtedly make a shell in less time than five, that is not the case with the making of a medical man. The consequence is that our supply of medical men cannot be expedited to meet the demand. For this reason also not only will the medical assistance required for the needs of the civil population be depleted, but as the war goes on the very strain thereof and the upset of those economic conditions on the stability of which the maintenance of a high state of individual efficiency depends will greatly increase the proportionate need for such assistance. While at all times prevention is infinitely more important than cure, the factors that tend to undermine the public health, and the evolution of conditions favouring the rise and spread of epidemic disease, are enormously increased during a prolonged war, as even a cursory study of history will demonstrate, so that undermanning of the sanitary service, whose duty it is to remove all causes and forestall all conditions that favour the spread of disease constitutes another problem of the first magnitude. A medical correspondent of the *Times* asks whether it may not be possible by a rearrangement of work to meet the demands and secure a margin of safety. Admitting the difficulties, he points out that while in the poorer-class districts the doctors are so fully occupied that no rearrangement is possible, in the suburban areas of large towns are to be found a considerable number of young men with comparatively little work, who are engaged in the building up of a practice. Such a practice when established represents invested capital, but, unlike the capital of an established commercial concern, it is almost purely personal, and is transferable in only a limited degree, tending to evaporate with the departure of the creating personality. Where, therefore, a practice is only in course of establishment it may be presumed that organised effort would have the effect of setting free a considerable number of such young men. The medical work might be centred in the hands of a few selected physicians already established there whose whole energies would be required, and thus a great waste of waiting time, which at present the nation cannot afford, would be obviated. The necessary adequate organisation might perhaps come through State intervention, for, among other things, it is clear that the assurance of some form of compensation on the recurrence of normal conditions would be necessary for those who have been dispossessed of their entire capital, which comprises mainly the time, labour, and money expended in the building up of an intangible and untransferable connexion, consisting of a personal attachment to themselves based on the estimate they have been successful in establishing of their own skill and capacity. Especially is this the case with those whose dependents have absolutely nothing outside of this on which to rely.

THE BRITISH CASUALTIES.

On Wednesday afternoon Mr. Asquith informed the House of Commons that the total British casualties in the French and Mediterranean Expeditionary Forces, including the Territorial, Overseas Dominions, and Indian contingents, up to the end of May comprised 10,955 officers and 247,114 non-commissioned officers and men killed, wounded, and missing. Of these, 3327 officers and 47,015 men have been killed. The figures, which do not refer to the navy, are not higher than had been anticipated by those who have followed the course of the war carefully, but they will serve to bring home to the public in a forcible and even heart-rending way the magnitude of the struggle in which the British Empire and our Allies are engaged. They also explain the urgent demand for medical assistance, and the need that this assistance, as it is forthcoming, should be used to the best advantage, every care being taken to see that full value is extracted from the supply.

THE TREATMENT OF WOUNDS IN WAR.

In the second number of the recently established *Journal of the Royal Naval Medical Service* appeared a paper detailing the results of a large number of experiments which had been conducted under the superintendence of a committee consisting of Sir William Watson Cheyne, Fleet-Surgeon P. W. Bassett-Smith, and Mr. Arthur Edmunds. The work of the committee dealt with the question of the prevention of the growth of septic organisms in a wound, and a very large number of experiments were made in order to investigate the rate of diffusion of various antiseptic substances through blood-clot, agar, and portions of tissue. Many very ingenious expedients were devised in order to test thoroughly the antiseptic value of various substances, and so much care was taken that the results may be accepted with confidence. The object of the investigation was to study the best method of dealing with wounds in the interval between the infliction of the wound and the arrival of the patient at a dressing station or field hospital, where the wound can be properly attended to—an interval not infrequently of several hours and sometimes even of days. The mere application of a field dressing over the wound, with or without cleansing of the surface or of the skin around, can have little effect on the spread of infection in the interior of the wound, though it will certainly tend to prevent the entrance of fresh infective material. It is clearly therefore desirable, if possible, to devise a method of inhibiting the growth of bacteria even in the depths of the wound. The material employed must be capable of diffusing through blood-clot, and to a certain extent also through the tissues, so that it may be capable of reaching the septic organisms which have invaded the wound. In the paper will be found a very full account of the experiments performed, and we need only mention their results. The committee decided that on the whole the most suitable antiseptic seemed to be a mixture of salicylic and boric acid, and that the most suitable application was a mixture of salicylic acid and boric acid, and that this was best applied as a powder to be dusted over the wounds thickly, while a cresol paste 20 per cent. in lanolin and wax base should be injected into the interior of wounds. The cresol paste is contained in paint tubes with nozzles two inches in length, so that it can be injected into the interior of the wound. So far the method has been employed only in a few cases in man, but it has been decided to make an extended trial of it, and therefore the material has been supplied to the navy. It is clear that it is only by an extended trial that the efficacy of the treatment can be established.

In the present issue of THE LANCET appears a rather trenchant criticism of the method by Mr. J. Godfrey Saner, who points out certain objections to its employment. The first objection is that the use of the paste prevents drainage, which is of so much importance in all septic wounds, and the second is that the method is not based on results obtained in actual wounds but on experiments in the laboratory. As to the interference with drainage, it may be said that the method does not inhibit the use of drainage tubes, and in fact in one case reported in the paper in which the method was employed a drainage tube was used. We fully agree that it is essential that in any deep wound there should be ample arrangement for drainage, otherwise the septic material is pent up and severe septic complications may result. The other objection, that the method is not based on the results in actual wounds, is puzzling, for the trial is being made, and the results will be examined with the greatest interest. The method has been elaborated with extreme care in the laboratory, and the names of the committee are a guarantee that the procedure suggested is at least based on careful experimental data. We know that Mr. Saner's views are not peculiar to himself, and, indeed, we have received communications to the same effect from others; but the probability is that there is not yet sufficient evidence forthcoming to warrant any decision.

Modifications in the Iodine Treatment of Wounds.

Dr. Douglas H. Stewart, a New York surgeon, has suggested employing as an agent in the treatment of wounds a combination of calomel and tincture of iodine in the proportion of 1 to 1000. The calomel forms iodide of mercury. For washing and dressing wounds 1 drachm of this solution is diluted to 2 ounces in water. The wound is cleaned and filled with the solution, toilet paper being employed for swabbing and, when folded and soaked with the solution, for draining. The wound is covered with soaked toilet paper, and over this a layer of dry toilet paper is placed and then bandaged with gauze or other material. It is claimed that toilet paper answers well for the purpose, inasmuch as it is porous and absorbent, and serves as an excellent draining medium; it does not adhere to the wound, and does not spread, curl, or unravel into threads. In aseptic procedure the wound is washed with the iodine-mercury solution, and drained with a strip of gauze fried in lard at a temperature of 175° C., and bandaged as usual. The following is the author's description of his technique.

> The advantage of having the gauze covering fried in lard is that lard can be brought to a very much higher temperature than water, and consequently germs and spores will be more surely destroyed. Also the gauze permeated with lard can be stripped off the wounds without causing pain and without injuring the surface of the wound and thereby impeding granulation and healing. This mode of treatment is applicable to all wounds which are infected and will be of great value in the present campaign. Success in treating wounds by this method has followed hospital practice.
>
> The combination intensifies the antiseptic action of the iodine without producing any escharotic effects. It appears that at the seat of war in France it is extremely difficult, in many cases impossible, to disinfect wounds thoroughly owing to the presence of anaerobes, such as the organisms of tetanus, malignant œdema, and B. aerogenes capsulatus. In particular wounds have been very frequently infected with the spores of tetanus. Most of the antiseptic agents employed are impotent against the organisms of tetanus, and if this combination will destroy the anaerobes it should be of the greatest service. There are three points to be considered. 1. The combination of calomel and iodine, making an antiseptic of greater strength by far than iodine alone. 2. The use of toilet paper as first dressing, it being non-adhesive, absorbent, and a good draining medium. 3. The practice of employing gauze boiled in lard up to a temperature of 347° F. as a first dressing, it being non-adhesive, and the temperature to which the lard can be raised being capable of killing germs and spores. The application of the ordinary tincture of iodine produces a tanning effect upon living tissue and affords a roof or shelter to anaerobes which may penetrate a little beyond the point of actual contact. The character of cases already treated resembles in many respects wounds produced in battle; of course, gunshot wounds being excepted.

The same surgeon, Dr. Douglas Stewart, referring to the method of treating infected wounds: (1) with hydrogen peroxide, (2) with tincture of iodine, and (3) bandaging with gauze pads and strips, says every one of these three steps may be improved upon. He uses sodium perborate in the place of hydrogen peroxide.

> A saturated solution of this salt (about 2½ per cent.) may be quickly made by adding to a cup or other vessel full of water a little greater quantity than can be dissolved, using the residue as an index of saturation, and this solution may be poured into a wound in the identical manner or mode that is employed with the use of H_2O_2. Effervescence is not synonymous with efficiency, and if the perborate solution yields rather less bubbling its well-known bactericidal effects would tend to prove that some of its gas was more profitably expended than merely escaping into the air. The solution is alkaline, but perishable. The powder form is, however, very stable. Consequently a small package (say, ¼ to ½ ℥) could be easily carried by each soldier. Sufficient of this could be dissolved in his cup, and the solution poured into the fresh wound by the man himself or one of his comrades, and the remainder of the treatment left for more skilful hands. The tincture of iodine, when applied to a wound in the same or a similar manner, burns like fire, it slows healing, and instead of affording protection against anaerobic infections seems rather to roof over and afford them shelter. Were our forebears so very far wrong in expressing approval of "laudable pus," because open septic wounds with abundant streptostaphylococcus overgrowth are not ideal homes for the germs of tetanus, but rather unfriendly or unfavourable environments?

Shuford's solution was planned for hypodermic use. Its formula is: Sod. bibor., acid. salicyl. aa ʒi., acid. carbolic. ʒiii., glycerin. ℥i. This is too strong for a wound application, though he has used it when all the conditions apparently (certain soils, toy pistol wounds, &c.) promised tetanus, but the wound will slough if it is applied more than once; consequently it has been modified to sod. bibor., acid. salicyl., acid. carbol., aa ʒiii., glycerin. ℥iss., aq. q.s. ad ℥ iv. The wound should be filled with this as it is germicidal, analgesic, and altogether an improvement over iodine.

The growth of granulations through the meshes of a gauze bandage renders sticking and tearing off necessary but uncomfortable accompaniments to its removal. Sheets of toilet paper (wood-pulp) may be folded or rolled into drains or lamp-wick shapes, the wound bridged diagonally or longitudinally with these which are to be roofed over with smooth sheets, and then gauze, put outside of and over all, will not stick, as there is a shield between it and the growing granulations; or if the paper does adhere it may be quickly softened and washed away by sponging with warm water and washing soda (¼ per cent.). Further attention is facile and agreeable to all concerned because removal has not caused additional trauma.

Military Hospitals at Milan.—A Swiss correspondent sends us an interesting description of Milan in war-time. "Milan," he says, "is preparing to receive and to look after the greatest possible number of wounded soldiers. Thanks to the generosity of some of the large city institutions and of numerous citizens 20 military hospitals, all furnished according to the requirements of modern medical and surgical science, have been organised, one of which, containing 400 beds, is installed in the seminary of the archbishopric. All the hospitals are linked up by tramways with the railway stations, and since the lines are of the same gauge the wounded will be conveyed without delay or change of vehicle from stations nearest the firing line to the hospital doors. Five gradients leading from the Milan railway station have been built and the invalids will be conveyed along one or other of these gradients according to the categories of sick or wounded they belong to. The installation of the hospitals has been organised in the same practical manner. The principal communes in the neighbourhood have joined in the work with the result that Milan and the surrounding district have placed 25,000 beds at the disposal of the army. The problem of personnel has been very easily solved for the population has offered a more than sufficient number of volunteers, all of whom readily accept the task allotted be it ever so modest. This municipal hospital service has been organised side by side with that of the efficient Italian Red Cross Society. Milan has profited by the past eight months to organise a sanitary service based upon the knowledge gained from battlefield experiences. What Milan has done has been done also with equal enthusiasm by other towns in Northern Italy. The organisation of the hospitals and the training of the staffs began at the end of last year, when well-informed and clear-sighted people realised that the participation of Italy in the war was inevitable."

Vacancy for a Medical Officer.—We are asked to state that a vacancy occurs for a medical officer willing to go on foreign service, to be attached to the Royal Engineers, East Anglian Division (T.F.). Usual pay and allowances for Territorial Force, R.A.M.C. Apply, Medical Officer in Charge, Royal Engineers, Radlett, Herts.

Wounded Allies Relief Committee.—The committee has received a report stating that the excellence of the French railway system and the improvements in emergency treatment make it possible for men to cover the 400 miles between the trenches and the hospital at Limoges in rather less than 30 hours. The Limoges hospital, which accommodates 150 patients, has received the warmest praise from General Delorme, of the French Medical Service, and the French Government has given 3000 francs for a hut to accommodate 20 more patients. Out of 600 cases treated there have been only 16 deaths. The hospital is now devoted exclusively to French wounded, for owing to the differences in religion the Government has found it advisable to provide special hospitals for native troops. The English are splendidly looked after in their own hospitals. The administrator appeals for gifts of tea, glass cloths, bath and roller towels, and slippers with leather soles, which may be sent to the Wounded Allies Relief Committee, Sardinia House, Kingsway, W.C., or to the Hôpital Militaire Anglais, Limoges, France.

The committee has opened a Kensington branch at 93, Lexham-gardens, Kensington, W., where a spacious house has kindly been lent rent free. The whole output of hospital equipment goes to the committee's hospitals, of which there are now three in France and two in the Balkans. In its first four days of working the branch has had the daily assistance of 100 ladies, but it can accommodate as many more, and would welcome other workers. The officials also warmly invite the public to call and see the work in progress.

The Depage Hospital, La Panne.—We are informed that a newly finished building, containing 300 beds, belonging to Dr. Depage's hospital was entirely destroyed by fire on the night of June 6th. No lives were lost.

Increased Hospital Accommodation for Wounded Soldiers in Dublin.—Through the generosity of Lord Iveagh the hospital accommodation for wounded soldiers in Dublin is about to be increased by 367 beds. Of these 200 will be in an annexe to the King George V. Military Hospital which Lord Iveagh has promised to build. Room for the remainder will be found in unused wards in the several Dublin hospitals.

The War and the Canadian Medical Association.—A Canadian correspondent writes: "The annual meeting of the Canadian Medical Association, which was to have been held this year in July in Vancouver, B.C., has been cancelled, as also has been the annual meeting of the Canadian Association for the Prevention of Tuberculosis, in the same city, about the same time. This is on account of so many prominent officers and members being away in Europe. The editor of the Journal has taken a medical commission. The general secretary of the association is with the McGill University General Hospital. Members of the finance committee and of the executive council are also serving abroad. In the meantime the affairs of the association and the Journal are being conducted by Dr. G. G. Campbell and Dr. J. W. Scane (Montreal). The association will have a strenuous year, but in the hands of these two such able men the best possible will be done for the association in the circumstances, and the association is very grateful to them for the proffer of their unpaid help."

The British Red Cross and the St. John Ambulance Association.—It is announced that a public meeting will be held on Wednesday next, June 16th, at 3 P.M., at the Mansion House, in aid of the funds of these institutions. The speakers will include Lord Lansdowne and Sir Edward Clarke.

Lady Wolverton calls attention to the fact that the demands upon the Red Cross Society are very heavy and that house linen and garments, both cotton and woollen, are wanted in large quantities, the garments most urgently needed being shirts and pyjamas—for summer wear,—vests, pants, handkerchiefs, and socks.

The Gretna Railway Disaster: A Military Train.—Sixty-six men of the Royal Scots injured in the Gretna railway disaster were brought to Edinburgh from the hospitals in and about Carlisle, and were taken to Craigleith Military Hospital, arriving at the Waverley station about 3.30. They travelled by the North British Railway in a Territorial military train recently fitted up by Mr. William Whitelaw, chairman of the North British Railway. It consists of seven vehicles, two of which contain cots, and has many advantages over the ordinary hospital train. Two tiers of cots are swung from the roof of the carriage in a manner similar to that in use on naval hospital ships, which eliminates vibration. Indiarubber fenders prevent the cots from coming into contact with the sides of the carriage when the train is in motion. An excellent feature of this type of train is that from the moment the wounded soldier is put in his cot until he is laid in bed in hospital he never leaves the cot, thus obviating one of the drawbacks of permanently fixed beds. The train, which includes a dining-car, was in charge of a R.A.M.C. officer, with two Red Cross sisters and R.A.M.C. orderlies; three Red Cross lady cooks prepared the food.

This was the first time the train had brought men north to Edinburgh. Hitherto it has been used to remove naval patients from Queensferry to other hospitals, but it is expected that in future greater use will be made of it in bringing wounded soldiers to Edinburgh. After the terrible railway accident the work of getting the men who could walk to the motor-cars was quickly accomplished, but there were others who had to be lifted from the train to the motors, and not a few limped badly. Injuries from burns were common. There were 26 cot cases.

SUPPRESSION OF THE BELGIAN RED CROSS BY GERMANY.—At the request of the Belgian Legation in London the Press Bureau has made public the fact that Baron von Bissing, the German Governor-General of the occupied provinces of Belgium, by a mandate dated April 14th, dissolved the Belgian Red Cross Central Committee and forcibly took possession of the funds and archives of the society, delegating Count B. von Hatzfeld to administer the institution. The Governor-General had previously demanded the help of the Belgian Red Cross for an institution he proposed to found for aid and protection to working women. The Red Cross Society refused on the ground that its objects were not within the scope of Red Cross work, in which they were supported by the International Red Cross Committee at Geneva.

OFFICIAL RESPIRATORS.—It is announced from the War Office that an improved type of respirator has been adopted on the recommendation of a special expert committee, and that there are ample supplies of this pattern available at the front. No unofficial help, therefore, is needed in this matter.

REST HOUSES FOR MILITARY NURSES.—The Duke of Portland and Lord Plymouth issue a weighty appeal in support of a hostel where nurses can be temporarily lodged while resting from their labours or awaiting orders which it is proposed to establish in close connexion with Queen Alexandra's War Fund for Nurses of the Red Cross and the Order of St. John of Jerusalem. It will serve as a clearing house also, nurses needing serious attention being sent to hospitals, others undergoing only dental or minor treatment remaining in the hostel, while yet others would be put into communication with the many kind people who are willing to offer them hospitality. During the war its advantages should be free. When the war is over it is hoped that it will remain as a permanent hostel where nurses can live at a moderate cost in congenial company. Subscriptions may be sent to the honorary treasurers at 3, Grosvenor-square, W., cheques crossed "London City and Midland Bank."

Lieutenant Andrew Philip, who had only recently given up his post as medical inspector of schools for the Keighley district of Yorkshire to take a temporary commission in the Royal Army Medical Corps, was suddenly taken ill after his first parade and fell, fracturing his skull. He was removed to the Royal Infirmary, Hull, where he died the following day.

PAYMENT OF CIVILIAN MEDICAL PRACTITIONERS FOR ATTENDANCE ON SOLDIERS' WIVES AND FAMILIES.—A medical correspondent, signing himself "Sine Premio Opifex," writes that seeing in THE LANCET Mr. Tennant's remarks about the various duties that medical men might perform in the war and the payments they might expect, he wrote to the War Office that he had attended the wives and children of a good many soldiers and supplied them with medicines, &c., at his own expense, and asking to whom he could render his account. He encloses the ensuing correspondence—viz., a letter dated April 14th, 1915, stating that the engagement of medical men for part-time service is in the hands of the local authorities, and directing him to communicate with the Deputy Director of Medical Services, Headquarters, Southern Command, Salisbury; a copy of his letter in accordance therewith asking if he may send his account there, and a reply therefrom stating that it is regretted that fees cannot be claimed by him as he does not come under paragraph 496 of the Regulations of the Army Medical Service, which reads: "The wives of N.C.O.'s and men who are borne on the married roll, with their children and stepchildren (under 14 years of age), will when present with their corps or in receipt of separation allowance, be allowed medical attendance and medical comforts at the public expense only at stations where there is a medical officer, or when a civilian medical practitioner is engaged for attendance on the troops, and provided in each case that they reside within the prescribed radius (one mile)." It will therefore be seen that civilian medical men cannot claim fees for attendance on the dependents of soldiers unless they have been specially engaged for attendance on troops, and then only for visits if the soldier's wife and family live within a mile from the doctor.

Medical News.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—At the annual election of the Royal College of Surgeons the following were elected for the ensuing year:—President: Mr. F. Conway Dwyer. Vice-President: Mr. W. Taylor. Secretary: Sir Charles A. Cameron. Council: Mr. W. Stoker, Sir Charles A. Cameron, Sir L. H. Ormsby, Mr. R. D. Purefoy, Mr. H. G. Sherlock, Sir Charles B. Ball, Mr. J. B. Story, Sir Thomas Myles, Sir Arthur Chance, Mr. S. M'C. Boyd, Sir Robert H. Woods, Mr. R. Lane Joynt, Mr. R. B. M'Causland, Mr. T. E. Gordon, Mr. E. H. Taylor, Mr. A. J. M'A. Blayney, Mr. R. C. B. Maunsell, Mr. T. N. Smith, and Mr. W. I. Wheeler.

LIVINGSTONE COLLEGE.—Commemoration Day was celebrated on June 3rd, the chair being taken by the former Principal and Founder, Lieutenant C. F. Harford, R.A.M.C. The Principal said that the session had been a successful one, but the call for medical men was now more urgent, and the committee would probably be shortly deciding to discontinue college sessions until the declaration of peace, so as to free those remaining on the staff to help in the national crisis. Two members of the staff had already taken commissions. It was thought that possibly the college, with its beautiful grounds, would be accepted by the War Office as an auxiliary hospital. Lieutenant Harford spoke of how the war affected Livingstone College as a brotherhood—unbroken, even though some who had been trained there together were now technically regarded as enemies—and as a missionary agency. Although Livingstone College was an international college, those responsible for carrying it on were British men and women and therefore had national responsibilities, whence it was possible that it might be found necessary to close down for a time. The meeting was then addressed very shortly by seven old students of the college. Mr. F. H. Hawkins, LL.B., secretary of the London Missionary Society, in the concluding address, said that in the first ten years of the history of this mission in Central Africa, 11 of their missionaries died and 6 were invalided home, and with one exception were never able to return to their work. In the last 12 years they had not had a single death in the mission or a single case of a man being invalided home. The explanation was that men had learned what Livingstone College was teaching them—the care of their own health, hygienic conditions, the need for building their houses in a healthy position, for draining the land round their houses, and for taking care of their heads when out in the sun. The missionary societies were very grateful to Livingstone College for the splendid services it had rendered.

PRIESTLEY MEMORIAL LECTURES.—The sixth of these lectures, given under the auspices of the National Health Society, is announced to take place in the Barnes Hall of the Royal Society of Medicine, Wimpole-street, W., on Wednesday next, June 16th. The lecturer, Dr. A. E. Shipley, Master of Christ's College, Cambridge, will deal with the dangers of flies and lice in connexion with the war. Sir James Crichton-Browne will preside.

THE Board of Trinity College, Dublin, has appointed Miss Euphan Montgomerie Maxwell to the recently established Montgomery lectureship in ophthalmology. Miss Maxwell is a graduate in medicine and surgery of the University of Dublin, a Fellow of the Royal College of Surgeons in Ireland, and holds the position of assistant surgeon and pathologist at the Royal Victoria Eye and Ear Hospital, Dublin.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Parliament and the War.

ALL the attention of Parliament is now absorbed in matters arising out of the war. The Coalition Government has met the House of Commons, and since the resumption of business after the Whitsuntide recess the energies of Parliament have been devoted to passing the Ministry of Munitions Bill.

British Casualties in the War.

The Prime Minister states that the casualties in the French and Mediterranean Expeditionary Forces (including the Territorial Force and the Colonial and Indian contingents) to May 31st are as follows:—

	Officers.	Other ranks.
Killed	3,327	47,015
Wounded	6,498	147,482
Missing	1,130	52,617
Total	10,955	247,114

The total for all ranks is thus 258,069. The Prime Minister has promised soon to give the complete figures for the Navy and Naval Division.

HOUSE OF COMMONS.

MONDAY, JUNE 7TH.

Proposed New Sanatorium for Middlesex.

Mr. NIELD asked the President of the Local Government Board whether, in connexion with the proposed building of a sanatorium by the Middlesex County Council at Mayland, Essex, he was aware that since the outbreak of war the council had decided that, while completing the purchase of the site, it was not desirable to apply for the consent of the Board to borrow a large sum of public money for the building, or to apply to the Public Works Loan Commissioners for a loan, or go to the public in competition with the Treasury at a time like the present when the whole resources of the country were urgently required to be husbanded or employed for the vigorous prosecution of the war in order to bring about its speedy conclusion; and whether such course had received his sanction.—Mr. LONG replied: I am aware of the resolutions passed by the county council at their meetings in January and May last. No sanction on my part is required in the circumstances described in the question, but if the honourable Member wishes to know whether I think that undertakings of this kind should be postponed in the present circumstances I can inform him that I do.

Mr. NIELD asked the Chancellor of the Exchequer whether he was prepared to sanction the advance by the Public Works Loan Board of the sum requisite for the erection by the Middlesex County Council of a large sanatorium for the treatment of tuberculosis.—Mr. MCKENNA answered: This matter is one for the President of the Local Government Board in the first instance and, having regard to the reply which he has given on this subject to-day, I do not think it probable that any application for a loan will come before the Public Works Loan Board or the Treasury for sanction at present.

Medical Officers of the Territorial Force.

Colonel GREIG asked the Financial Secretary to the War Office whether any steps were being taken to remedy the hardships of medical officers of the Territorial Force who had been mobilised with regard to promotion and the question of a gratuity.—Mr. FORSTER replied: I hope to be in a position to make a statement on this question before long.

TUESDAY, JUNE 8TH.

Medical Certificates for Sick Soldiers.

Sir J. D. REES asked the Under Secretary for War whether commanding officers had been instructed to accept certificates given by duly qualified medical men to sick soldiers on furlough residing at a distance of over two miles from military hospitals; if so, whether any such certificates had been ignored and the sick soldiers who obtained them punished; and, if so, whether such action was approved by the superior military authorities.—Mr. TENNANT answered: The rule in force is that when a man forwards a civil medical practitioner's certificate recommending an extension of furlough arrangements are made for his readmission to the nearest military hospital, where he will remain under treatment until he is fit to rejoin his unit or depôt. I am informed that no cases had come to notice prior to the issue of the instructions I have mentioned of civilian medical practitioners' certificates being ignored, either with or without the approval of the superior military authorities, once it had been ascertained beyond doubt that the certificates were genuine.

The Eyesight of Recruits.

Sir IVOR HERBERT asked the Under Secretary for War whether any arrangements had been made for the special treatment of recruits found to be suffering from defective eyesight caused by the conditions under which they had been industrially employed before enlistment which rendered them temporarily unfit for military service.—Mr. TENNANT answered: Men suffering from the severer forms of defective eyesight should not, of course, be enlisted, and if by any chance they have got into the army they should be discharged. Men suffering from the milder forms would receive the same treatment that they would have in civil life—i.e., correction of any error of refraction, tonic drugs, rest or modified exercises, and local treatment to the eye.

Discharges from the Army.

Sir IVOR HERBERT asked the Under Secretary for War whether the attention of the Secretary of State had been drawn to the large number of discharges from the new armies for physical and other causes; and whether any measures were being taken to prevent the enlistment of such discharged men and to retain their services for the industrial or agricultural operations for which they might be fitted.—Mr. TENNANT said in reply: The matter referred to in the first part of the question receives the constant attention of the military authorities. Men who have enlisted since the beginning of the war and have once been discharged are not accepted for re-enlistment, with the sole exception of those discharged on purely medical grounds whom the examining medical officer, with full knowledge of the cause of discharge, pronounces to be fit for service at home and abroad.

Meat Inspection.

Mr. WILLIAM THORNE asked the Financial Secretary to the War Office a question to elicit the conditions under which frozen meat for the use of the troops was inspected.—Mr. FORSTER replied: The scope of the inspection is well understood. All meat imported is examined and certified as free from disease at the port of shipment. Before issue to the troops it is passed by a board of officers, which includes an officer of the Army Service Corps.

WEDNESDAY, JUNE 9TH.

Medical Students and War Service.

Mr. MCCALLUM SCOTT asked the Under Secretary of State for War whether the arrangements previously announced, whereby medical students in their final year of study who had only their final examinations to pass might be released from combatant corps if they applied in order to complete their medical studies and qualify for medical service, had been altered; and, if so, in what respect.—Mr. TENNANT answered: The ruling applied to medical students who were serving in the ranks and has not been altered.

Appointments.

Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

BARFORD, A. M., M.R.C.S., L.R.C.P. Lond., D.P.H., has been appointed Medical Officer of Health and School Medical Officer for Newark.

JOHNSON, J., M.B., C.M. Glasg., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Birtley District of the county of Durham.

JONES, PETER, M.D. Edin., has been appointed Medical Officer of Health to the Abergele and Pensarn Urban District Council.

BAE, HARRY, J., M.B., Ch.B. Aberd., has been appointed Tuberculosis Officer for the county of Aberdeen.

ROSS, V. A., M.B., C.M. Edin., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Harris District of the county of Inverness.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

When the application of a Belgian medical man would be considered the advertisers are requested to communicate with the Editor.

BIRKENHEAD BOROUGH HOSPITAL.—House Surgeons.

BIRMINGHAM CORPORATION CITY HOSPITAL, Lodge-road.—Temporary Female Assistant Resident Medical Officer. Salary £250 per annum, with board, residence, and washing.

BIRMINGHAM GENERAL DISPENSARY.—Resident Medical Officer, unmarried. Salary £250 per annum, with apartments, attendance, &c.

BIRMINGHAM AND MIDLAND EYE HOSPITAL.—Junior House Surgeon. Salary £100 per annum, with residence, board, &c.

BOLINGBROKE HOSPITAL, Wandsworth Common, S.W.—House Surgeon. Salary £100 per annum, with board-residence.

BRADFORD CHILDREN'S HOSPITAL.—House Surgeon. Salary £120 per annum, with board, residence, and laundry.

BRADFORD EDUCATION COMMITTEE.—Assistant School Dentist. Salary £300 per annum.

BRISTOL ROYAL INFIRMARY.—Throat, Nose, and Ear House Surgeon for six months. Salary at rate of £120 per annum, with board, apartments, and laundry.

BUENOS AYRES, BRITISH HOSPITAL.—Senior Resident Medical Officer, unmarried. Salary £275 per annum. Also Assistant Resident Medical Officer, unmarried. Salary £250 per annum, with board, lodging, &c.

BURY INFIRMARY.—Senior and Junior House Surgeons. Salary £175 and £150 per annum respectively, with board, residence, and washing.

BUXTON, DERBYSHIRE, DEVONSHIRE HOSPITAL.—Assistant House Physician for six months. Salary £100 per annum, with apartments, board, and laundry.

CARDIFF, WELSH METROPOLITAN WAR HOSPITAL, Whitchurch, near Cardiff.—Pathologist and Bacteriologist. Salary £1 per day, with board, apartments, and washing.

CARLISLE NON-PROVIDENT DISPENSARY.—Resident Medical Officer. Salary £200 per annum, with apartments (not board).

CIRENCESTER, GLOS., 1ST SOUTH MIDLAND MOUNTED BRIGADE FIELD AMBULANCE.—Two Medical Officers to complete 2nd Line (Territorial).

COVENTRY AND WARWICKSHIRE HOSPITAL.—House Surgeon. Salary as arranged. Also Third House Surgeon. Salary 6 guineas per week, with board and residence.

CROYDON UNION.—Assistant Medical Superintendent of Infirmary and Assistant Medical Officer of Workhouse and Children's Homes. Salary £225 per annum.

EVELINA HOSPITAL FOR SICK CHILDREN, Southwark, S.E.—Clinical Assistants in Out-patient Departments.

FOLKESTONE, ROYAL VICTORIA HOSPITAL.—House Surgeon. Salary as agreed, with board, residence, and laundry.

GREAT NORTHERN CENTRAL HOSPITAL, Holloway, N.—House Surgeon for six months. Salary at rate of £60 per annum, with board, residence, and laundry.

GUILDFORD, ROYAL SURREY COUNTY HOSPITAL.—House Surgeon. Salary £150 per annum, with board, residence, and laundry.

HARTLEPOOLS HOSPITAL.—House Surgeon. Salary £125 per annum, with board, washing, and lodging.

HEREFORD COUNTY AND CITY ASYLUM.—Locum Tenens Assistant Medical Officer. Salary £7 7*s.*, with board.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton. —House Physician for six months. Salary 30 guineas. Also Assistant Resident Medical Officer. Salary £100 per annum, with board and residence.

INVERNESS, NORTHERN INFIRMARY.—House Surgeon. Salary £150 per annum, with board, &c.

LEAMINGTON SPA, WARNEFORD, LEAMINGTON, AND SOUTH WARWICKSHIRE GENERAL HOSPITAL.—Second Resident Medical Officer. Salary £200 per annum, with board, residence, and laundry.

LIVERPOOL, WALTON INSTITUTION, Rice-lane, Walton.—Assistant Resident Medical Officer, unmarried. Salary at rate of £300 per annum, with board, &c.

MACCLESFIELD GENERAL INFIRMARY.—Resident Medical Officer. Salary £150 per annum, with board and residence.

MANCHESTER CORPORATION, BAGULEY SANATORIUM.—Superintendent. Salary £400 per annum, with house, coal, light, and washing.

MANCHESTER COUNTY ASYLUM, Prestwich.—Assistant Medical Officer, unmarried. Salary £250 per annum, with board, apartments, attendance, and washing.

MANCHESTER NORTHERN HOSPITAL FOR WOMEN AND CHILDREN. Park-place, Cheetham Hill-road.—House Surgeon. Salary £120 per annum, with apartments and board.

METROPOLITAN EAR, NOSE, AND THROAT HOSPITAL, Fitzroy-square, W. —House Surgeon. Salary £150 per annum. Also Honorary Anæsthetist and Honorary Clinical Assistant.

NEW ZEALAND WAR CONTINGENT ASSOCIATION, 25, Victoria-street, London, S.W.—Resident Medical Officer for New Zealand Auxiliary Hospital, Walton-on-Thames. Salary at rate of £7 7*s.* per week, with board.

NORWICH, CITY OF.—Assistant School Medical Officer. Salary at rate of £400 per annum.

NOTTINGHAM CHILDREN'S HOSPITAL.—Female House Surgeon. Salary at rate of £150 per annum, with apartments, board, and washing.

NOTTINGHAM GENERAL HOSPITAL.—Senior House Physician and Assistant House Physician. Salary at rate of £300 and £250 per annum respectively, with board, residence, and laundry.

OLDHAM COUNTY BOROUGH.—Assistant Schools Medical Officer. Salary £325 per annum.

POPLAR BOROUGH COUNCIL, BOW MATERNITY CENTRE.—Medical Practitioner for two and a half hour session every Thursday afternoon. Salary 21*s.* a session.

PORTSMOUTH ROYAL HOSPITAL.—House Surgeon for six months. Salary £150 per annum, with board, &c.

ROCHESTER, KENT, ST. BARTHOLOMEW'S HOSPITAL.—Assistant House Surgeon, unmarried, for six months.

ST. MARY'S HOSPITAL FOR WOMEN AND CHILDREN, Plaistow, E.—Assistant Resident Medical Officer. Salary at rate £90 per annum, with board, residence, and laundry.

SALFORD COUNTY BOROUGH.—Medical Officer for Maternity and Child Welfare work. Salary £300 per annum.

SALISBURY GENERAL INFIRMARY.—House Surgeon and Assistant House Surgeon, unmarried. Salary £150 and £100 per annum respectively, with apartments, board, lodging, and washing.

SCARBOROUGH HOSPITAL AND DISPENSARY.—Senior and Junior House Surgeons. Salary £100 and £80 per annum respectively, with board, residence, &c.

SHEFFIELD ROYAL INFIRMARY.—House Surgeon and Assistant House Physician. Salary £100 per annum, with board and residence.

SOUTHAMPTON, PARISH INFIRMARY, Shirley Warren.—Resident Assistant Medical Officer. Salary £250 per annum, with apartments, rations, washing, and attendance.

SOUTHWARK UNION INFIRMARY, East Dulwich-grove, S.E.—Assistant Medical Superintendent. Salary at rate of £250 per annum, with board, apartments, and washing.

STOCKPORT INFIRMARY.—Senior House Surgeon. Salary £200 per annum, with board, washing, and residence.

SWANSEA GENERAL AND EYE HOSPITAL.—House Physician. Salary £125 per annum, with board, apartments, and washing.

THROAT HOSPITAL, Golden-square, W.—Resident House Surgeon.

TINGWALL, WHITENESS, AND WEISDALE PARISH.—Medical Officer and Public Vaccinator. Salary £45 per annum.

VENTNOR, ROYAL NATIONAL HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Isle of Wight.—Assistant Resident Medical Officer.

WALSALL AND DISTRICT HOSPITAL.—Assistant House Surgeon and Anæsthetist. Salary £150 per annum, with board, residence, and laundry.

WEST BROMWICH AND DISTRICT HOSPITAL.—House Surgeon and Assistant House Surgeon, unmarried. Salary £150 and £120 per annum respectively, with residence, board, and laundry.

WEST HAM AND EASTERN GENERAL HOSPITAL.—Resident Medical Officer. Salary £160 per annum. Also House Physicians. Salary £120 and £100 per annum, with board, residence, and washing.

WIGAN, ROYAL ALBERT EDWARD INFIRMARY AND DISPENSARY.—Junior House Surgeon. Salary £150 per annum, with board, apartments, and washing.

THE Chief Inspector of Factories, Home Office, London, S.W., gives notice of vacancies for Certifying Surgeons under the Factory and Workshop Acts at Milngavie, in the county of Dumbarton; at Charlestown, in the county of Mayo; and at New Quay, in the county of Cardigan.

Births, Marriages, and Deaths.

BIRTHS.

CANE.—On June 3rd, at Orton Longueville, Peterborough, to Captain (R.A.M.C.) and Mrs. L. B. Cane, a daughter.

HODGES.—On June 5th, at Queen Anne-terrace, Plymouth, Barbara, wife of Lieutenant G. M. Hodges, R.A.M.C., of a daughter.

TEICHMANN.—On June 5th, at Sitka, Chislehurst, the wife of Captain O. Teichmann, R.A.M.C. (T.), Worcestershire Yeomanry, of a son.

MARRIAGES.

BRAHAM—WIBORG.—On June 5th, in London, Lieutenant Noel Braham, R.A.M.C., to Ruth, daughter of the late Ludvig Wiborg, of Brevik, Norway.

CARMICHAEL—HEPWORTH.—On June 3rd, at the Parish Church, Morley, Yorks, Donald Livingstone Carmichael, Ch.B., M.D., to Constance Margaret, eldest daughter of Dr. and Mrs. George Hepworth, of Clarence Lodge, Morley.

DAINTY—LOCKHART.—On June 5th, at Holy Trinity, Brompton, Lieutenant Ralph George Dainty, R.A.M.C., to Marjorie Kathleen, youngest daughter of the late William Castleton Lockhart.

WILSON—WHITWELL.—On June 1st, at St. Stephen's Church, Enfield, Lieutenant (temporary) Cecil William Wilson, R.A.M.C., to Mary Dorothy, daughter of Mr. and Mrs. Henry Whitwell, of Winchmore Hill.

DEATHS.

DANE.—On June 7th, at Bournemouth, Harold Dane, M.R.C.S., L.R.C.P. Lond.

ROSE.—On June 2nd, at a Nursing Home in London, Deputy Surgeon-General H. J. Rose, formerly in the 2nd (Queen's) and West Yorkshire Regiments, aged 82 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

BOOKS, ETC., RECEIVED.

BALE, JOHN, SONS, AND DANIELSSON, LIMITED, London.
A Guide to the Use of Tuberculin. By Archer W. R. Cochrane, M.B. Lond., F.R.C.S. Eng., Major I.M.S., and Cuthbert A. Sprawson, M.D., B.S. Lond., M.R.C.P., Major I.M.S. Price 5*s.* net.
Dental Directory, 1915. Enlarged edition. Price 3*s.* 6*d.* net.

The Medical Annual: A Year Book of Treatment and Practitoners' Index. 1915. Price 10*s.* net.

Notes, Short Comments, and Answers to Correspondents.

MRS. TIMOTHY BRADLEE'S EXPLOIT: A CORRECTION.

IN the *Boston Medical and Surgical Journal* of September, 1872, appeared the following note:—"On the 21st of August Mrs. Timothy Bradlee, of Trumbull County, Ohio, gave birth to eight children—three boys and five girls. They are all living and healthy, but quite small. Mrs. Bradlee has given birth to two pairs of twins. She was a triplet, her mother and father being twins and her grandmother the mother of five pairs of twins." This case in due course found its way into important publications, such as Gould and Pyle's "Anomalies and Curiosities of Medicine" and the paper on duplicate twins by Wider in the *American Journal of Anatomy*. Recently Dr. G. H. Parker, of Harvard University, determined to ascertain beyond doubt the authenticity of the case as it was so remarkable. He wrote to Mr. M. B. Tayler, clerk of the courts, Trumbull County, stating that further information concerning it would be gratefully received. The latter replied that on inquiry he found that there was no truth in the statement. It seems that a practical joker went into one of the local newspaper offices and set up an article which he succeeded in having printed in one or two copies of the paper. The article was then taken out and the type distributed. But one of the copies was sent to a New York journal. The consequences probably never entered the joker's imagination. American medical journals of the highest class gave currency to an absurdity which has passed into standard works. We cannot recall any similar instance in comparatively modern times in which an error of so obvious a sort has crept into medical literature. Having circulated so long and obtained such publication, it will probably be further copied. We are pleased to do our part in helping to prevent this.

WHAT IS A CONSULTANT?

To the Editor of THE LANCET.

SIR,—With regard to the case put by "Enquirer" in your issue of June 5th (p. 1214), the customary procedure varies according to locality. In the English provinces no one would feel doubtful. I remember being astonished three or four years ago when a patient told me Sir Blank Dash had attended him regularly during an attack of typhoid. The distance was much greater than from the Cavendish-square quarter to the Langham Hotel, while the fee per visit, since the man was a small publican, must have been considerably under 3 guineas. Indeed, in the provinces the consultant's only perceptible *differentia* is that he does not undertake midwifery, unless that and gynæcology be his main occupation. Even this is by no means an absolute rule, for I know of a recently appointed clinical teacher at a well-known provincial university, a man of middle-age, who does midwifery as a part of his general practice.

I am, Sir, yours faithfully,

June 8th, 1915. ONLOOKER.

THE GERMAN ARMY MEDICAL CORPS.

FOUR years ago the following note was published in THE LANCET on the inadequate supply of candidates for the German Army Medical Corps:—"The younger members of the medical profession in Germany are not as a general rule inclined to enter the Army Medical Corps, and the undoubted advantages which a medical man may obtain through holding a commission in the army are not sufficiently appreciated; the result is that candidates are not numerous, and there is some difficulty in filling the vacancies which arise in the ordinary course of events. The medical officers of the army have for the most part received their professional education in the Army Medical School, and for each year of gratuitous instruction in that establishment they are required to serve two years in the army; some of them, however, but these are a minority, study as civilians and afterwards join the Army Medical Corps. The civilians who become medical officers on active service are continually diminishing in number, so that many appointments which would properly be given to medical officers on active service in the junior grades have to be filled by civilians accomplishing their half year of compulsory military service." The causes of this state of things were considered to be insufficient remuneration of the junior grades, a feeling of personal independence not compatible with the requirements of military discipline, restriction of private practice through being so much away from home on military duties, and monotony of practice in garrison towns. To provide the army with trained specialists, assistantships in hospitals and clinics were reserved for army medical officers exclusively, but the officers in many cases who had been trained as specialists at the expense of the army left the service and settled as specialists in the towns.

The medical officers also complained that with respect to position and privileges they were at a disadvantage as compared with regimental officers of equivalent rank. As regards this question of rank we announced in THE LANCET of March 14th, 1914, that General von Falkenhayn, the Minister for War, attended a meeting of the Berlin Society of Army Doctors and informed the assembled medical men that the Emperor by a stroke of the pen had put an end to the sharp distinction between army doctors of whatever rank and the youngest combatant officer who has received a commission. This order gave them disciplinary rights—rights to ceremonial salutes, the right to wear the officer's scarf, and the right to be buried with military honours. The delicate question of precedence remained unsettled. The position in Germany, as with the Allies, has no doubt been altered since the above information was published, but it illustrates the evolution of the Army Medical Service in all lands, and its necessary recognition as an integral part of any army which must be recognised as such, and not as an arm which may be attached or detached and fostered or neglected as merely mechanical exigencies seem to dictate.

A TESTIMONIAL TO VACCINATION.

THE following extract from a letter recently received in England from a newspaper reporter in Calcutta has been sent to us by his mother. The letter gives many details as to the cases of small-pox in the hospital which have no particular medical significance, but his advocacy of vaccination is particularly forcible:—

"I suppose you would like to hear something about my attack of small-pox. Well, there is an epidemic of it in Calcutta just now, and a lot of Europeans (and tons of natives) are down with it. I must consider myself very lucky in having it in a mild form—so mild that I was convalescent in a few days after being admitted. After that it was simply a question of waiting until there was no possibility of anyone catching it from me. Jove! it was like being in gaol. Before I was attacked I was one of the silly fools (they can be called by no other name) who scoffed at vaccination; but after seeing what I have seen this past fortnight my views on that matter have entirely changed. There is not the slightest doubt that the two vaccination marks on my arm saved me from—well, perhaps the worst. In every instance the bad cases were those in which the patient had either never been vaccinated at all, or else not for many many years."

SILVER PAPER FOR CHARITY.

THE fact that there is money in unconsidered trifles is made plain in a recent issue of the *East Ham Echo*, which states that some time ago the sons and daughters of the readers of that paper were enrolled into a league to show the young idea how to combine. It appears that about 18 months ago it was suggested that the members should collect silver paper, which could be sold and the money sent to the East Ham Hospital. The advice was taken and the young people set about collecting the silver paper. Since then members have sent in their collections on three separate occasions, with the result that the sum of £8 15*s.* has accrued to the hospital.

A PORTABLE SHOWER-BATH.

THE tonic and exhilarating effect of a cold shower-bath on the person whose circulation reacts is well known. There is experienced a shock, the cutaneous vessels at once contract and send the superficial blood-supply inward, while respiration is momentarily arrested, and then slowed and increased in depth. The return of the blood in increased volume to the surface is the reaction which gives a sensation of warmth and general well-being. The stimulus is greater when a shower-bath with some force is used. To meet those instances in which the luxury of a shower-bath is not a part of the domestic bath equipment Messrs. Bostel and Sons, of Ebury-street, London, S.W., have introduced a portable shower-bath which answers the requirements very well. It consists of two containers 10 inches in diameter and 4 inches deep fitting within each other, one a plain round metal vessel and the other a similar appliance, but with its bottom perforated. The first container is filled with water at any desired temperature. The perforated container with the perforations upward is then placed over it, which it encircles like a telescopic tube. On now inverting the appliance so that the perforated disc is underneath the water is discharged in a smart shower. It is important that the shower should be smart and not a dribble, as otherwise the effect on the system is depressing rather than stimulating. This is done by four air tubes fixed in the perforated container so that the air freely entering at the top allows the water to escape with a rush. It is very neatly made and moderately priced. While it is correctly described as portable it incidentally serves as a receptacle for articles of toilette as, for example, a sponge, comb and brush, so that the space it occupies can be utilised in the travelling kit. It is suggested that its use in a campaign would be much appreciated, and no doubt it would. Many will be glad of it, however, as an adjunct to the domestic bath equipment.

RHUBARB POISONING.

F. W. (London) writes: With reference to the letters on this subject which have recently appeared in THE LANCET, everyone knows of cases where the eating of rhubarb has caused severe diarrhœa and sickness and a sensation of having been poisoned. One old gentleman, after some uncomfortable experiences, refuses to eat the "forced" rhubarb, but always waits for what he terms the "field" rhubarb. He had been informed that a good deal of forced rhubarb was grown in coal-mines where it was warm and the dung of the pit ponies was used as manure. I do not know whether there is, or ever was, any truth in this, but it is the reason of his abstinence.

AN INDEMNITY POLICY FOR THE MEDICAL MAN.

A NOVEL feature of insurance is introduced by the Norwich Union Fire Insurance Society, whereby a policy can be taken out which provides, in addition to the usual benefits for accidental loss of life, limbs, or sight, complete indemnity against financial loss incurred by accident or sickness, including diminution in earnings or salary, and the cost of employing a locum tenens. The amount of the indemnity is decided upon by the assured, and he pays the premium accordingly. Under the scheme there is no question of getting a certain weekly allowance, be the temporary disablement trivial or severe; the definite amount of indemnity is stated on the face of the policy, and that is the amount upon which the assured can draw, as and when required, for medical fees, nursing-home charges, travelling and other expenses of convalescence, additional household expenses, and payment of locum tenens, irrespective of the period of disablement. The common sense of this arrangement suggests that it might have been made a regular feature of insurance years ago. Full particulars of benefits and premiums can be obtained on application to the society at St. Giles-street, Norwich.

SCOPOLAMINE.

MANY notices have lately been appearing in the lay press with reference to the use of scopolamine anæsthesia, or so-called "twilight sleep," in obstetrics. A few years ago the Council on Pharmacy and Chemistry of the American Medical Association came to the conclusion that scopolamine and hyoscine are synonyms for the same alkaloid. THE LANCET of Feb. 10th, 1906 (p. 393), contained an annotation entitled "The Danger of Using Scopolamine as an Anæsthetic," in which it was stated that the anæsthetic was losing favour in France, and warnings were also given regarding the dose and administration of the drug. Apparently since then little has been published concerning the dangers, if we may judge from the recent campaign in the lay newspapers in its favour. It may not be generally known that "scopolamine" owes its name to G. A. Scopoli (1723–1787), a naturalist and chemist who was born at Cavelese, Tyrol, and whose name Linnæus gave to a genus of solanaceous plants resembling hyoscyamus, thence termed Scopolia.

THE HARRIS GAS FIRE.

Mr. Reginald P. Harris, of the Commercial Gas Company, Poplar, London, E., has introduced an interesting novelty in the design of a gas fire. Instead of the radiants consisting of the ordinary upright clay tubes they are curved, so that the front of the fire, viewed from the side, is shaped thus C. The effect of this is to concentrate more radiant heat downwards, and this is obvious, inasmuch as when a person stands a short distance from the fire he soon finds his boots and feet getting warm. That, of course, presents certain advantages, particularly as people so often sit near the fire with their feet close to the fender. We were inclined to believe at first that this arrangement would interfere with the hygienic working of the fire, as this particular construction, which means that the radiants bulge well in front of the fire, seemed likely to result in the escape of combustion products into the room. On applying, however, the test for hygienic efficiency, described in our issue of Feb. 7th, 1914, this fire showed no escape of combustion products into the room whatever, even when no elbow or flue was attached to the exit nozzle. This fire, therefore, may be added to the list we have published of those gas fires which have satisfactorily passed THE LANCET test. The Harris gas fire is made by the Vulcan Stove Company, Exeter.

SOMALILAND STATISTICS.

A REPORT on the affairs of this Protectorate (established in 1884) for the year 1913–14 has been presented to Parliament. It states, *inter alia*, that no reliable information is forthcoming as to the Somali population of the country at the present time, though 300,000 is given as an approximation. A census taken in 1911 of the alien community in the three coast towns of Berbera, Bulhar, and Zeyla showed the following results:—Europeans, 26; Indians, 741; Arabs, 1857; mixed, 789. There is a general hospital at each of the three towns named. At Berbera there is accommodation for 42 beds, at Bulhar for 4, and at Zeyla for 6. There is a dispensary attached to each of the hospitals, and in the aggregate there were 38,987 attendances during the year. The climate of the Protectorate is chiefly remarkable for its very dry character. In the interior it is healthy, generally speaking, throughout the year, but the same can scarcely be said of the coast belt. Here during the "Kharif"—i.e., the months of June, July, August, and not infrequently half of September—the atmospheric conditions are very trying for Europeans, and the effect on the nervous system is most pronounced. Terrific gales of sand-laden wind are then prevalent and the heat is intense, with the thermometer registering 105°–115° F. in the shade at mid-day, and seldom falling below 100° at night. Most of the sickness, however, occurs during the months immediately preceding and immediately following the "Kharif." During the months of November, December, January, and February the climatic conditions of the coast greatly improve.

THE REMINGTON "J."

THERE has recently been put upon the market by the makers of the well-known Remington typewriter a new model known as the Remington "J," with visible writing, which will do all the work of its predecessors, and has the advantages of being about half their weight and half their price. A practical trial of this new member of the Remington family convinces us of its utility for the medical man, who will find it to be a neat, handy, and, in its specially designed carrying-case, a very portable machine, capable of being set up anywhere at a moment's notice by merely throwing back the cover, and as speedily removable when desired. The Remington Typewriter Company, 100, Gracechurch-street, London, E.C., will send a booklet to those interested, on application.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

METEOROLOGICAL READINGS.

(Taken daily at 9.30 a.m. by Steward's Instruments.)

The following magazines, journals, &c., have been received:— Journal of Laryngology, Rhinology, and Otology, British Journal of Children's Diseases, Edinburgh Medical Journal, St. Bartholomew's Hospital Journal, British Dental Journal, Tropical Diseases Bulletin, Proceedings of the Pathological Society of Philadelphia, Report on Researches on Sprue in Ceylon, Medical Review, South African Medical Record, Cornell University Medical Bulletin, Pediatrics, Dublin Journal of Medical Science, Charing Cross Hospital Gazette, &c.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY, Burlington House, London, W.

THURSDAY.—Papers:—Mr. W. L. Balls and Mr. F. S. Holton: Analyses of Agricultural Yield. Part II. The Sowing-date Experiment with Egyptian Cotton, 1913 (communicated by Dr. F. F. Blackman).—Mr. E. J. Russell: Soil Protozoa and Soil Bacteria (communicated by Mr. H. T. Brown).—Prof. W. M. Hicks: On the Enhanced Series of Lines in Spectra of the Alcaline Earths.—Prof. H. F. Baker: On Certain Linear Differential Equations of Astronomical Interest.—Prof. K. Pearson: On the Partial Correlation-ratio.—Mr. S. Skinner and Mr. F. Entwistle: The Effect of Temperature on the Hissing of Water when flowing through a Constricted Tube (communicated by Sir W. N. Shaw).—And other papers.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

THURSDAY.

SECTION OF DERMATOLOGY (Hon. Secretaries—S. E. Dore, A. M. H. Gray): at 5 P.M.

Exhibition of Cases (at 4.30 P.M.):

Dr. G. Pernet: (1) Morphœic Sclerodermia; (2) Extra-genital Primary Chancre.

Dr. Parkes Weber: Blue Tattooing of the Skin from Hypodermic Injections in a Morphinist.

Dr. E. A. Cockayne (introduced by Dr. Parkes Weber): Congenital Sclerodermia with Sclerodactylia.

Dr. G. F. Stebbing (introduced by Dr. Parkes Weber): (1) Case for Diagnosis; (2) Case for Diagnosis (?) Lichen Planus of Long Duration.

Dr. D. Walsh: Case for Diagnosis: with microscopical sections.

Mr. Laming Evans (introduced by Dr. Phineas S. Abraham): Acute Atrophodermia.

Dr. Phineas S. Abraham: Case of "Oriental Sore" (after treatment): with microscopical sections.

SOCIETY OF TROPICAL MEDICINE AND HYGIENE, 11, Chandos-street, Cavendish-square, W.

FRIDAY.—8.30 P.M., Annual General Meeting. Paper:—By the late Dr. R. M. C. Linnell: Some Observations on Malaria on Rubber Estates. Discussion:—Quinine Prophylaxis in Malaria.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East.

THURSDAY.—5 P.M., Croonian Lectures:—Surgeon-General Sir David Bruce, C.B.: Trypanosomes causing Disease in Man and Domestic Animals in Central Africa. (Lecture I.)

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Dr. Simson: Diseases of Women. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. D. Armour: Operations. Dr. Pritchard: Bacterial Therapy Department. Mr. B. Harman and Mr. Gibb: Diseases of the Eye.

TUESDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations. Dr. Simson: Diseases of Women. Mr. Gibb: Diseases of the Eye.

THURSDAY.—9 A.M., Dr. Bernstein: Bacterial Therapy Department. [illegible] P.M., Medical and Surgical Clinics. X Rays. Mr. D. Armour: Operations. Mr. B. Harman: Diseases of the Eye.

FRIDAY.—10 A.M., Dr. Simson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Eye Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY.—Clinics:—10.30 A.M., Surgical Out-patients (Mr. E. Gillespie). 2.30 P.M., Medical Out-patients (Dr. T. R. Whipham); Gynæcological Out-patients (Dr. Banister). 3 P.M., Medical In-patients (Dr. R. M. Leslie).

TUESDAY.—2.30 P.M., Surgical Operations (Mr. Carson). Clinics:—Medical Out-patients (Dr. A. G. Auld); Surgical Out-patients (Mr. Howell Evans); Nose, Throat, and Ear Out-patients (Mr. H. D. Gillies). Radiography (Dr. Metcalfe). 3.30 P.M., Medical In-patients (Dr. A. J. Whiting). 4.30 P.M., Clinical Demonstration:—Dr. A. J. Whiting: Selected Medical Cases.

WEDNESDAY.—Clinics:—2.30 P.M., Throat Operations (Mr. Gillies). Children Out-patients (Dr. T. R. Whipham); Eye Out-patients (Mr. R. P. Brooks); Skin Out-patients. 5.30 P.M., Eye Operations (Mr. R. P. Brooks).

THURSDAY.—2.30 P.M., Gynæcological Operations (Dr. A. E. Giles). Clinics:—Medical Out-patients (Dr. A. J. Whiting); Surgical Out-patients (Mr. Carson); Radiography (Dr. Metcalfe). 3 P.M., Medical In-patients (Dr. R. M. Leslie).

FRIDAY.—2.30 P.M., Surgical Operations (Mr. Howell Evans). Clinics:—Medical Out-patients (Dr. A. G. Auld); Surgical Out-patients (Mr. E. Gillespie); Eye Out-patients (Mr. R. P. Brooks).

THE THROAT HOSPITAL, Golden-square, W.

MONDAY.—5.15 P.M., Special Demonstration of Selected Cases.
THURSDAY.—5.15 P.M. Clinical Lecture.

For further particulars of the above Lectures, &c., see Advertisement Pages.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed " To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed " To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.			
One Year	£1	1	0
Six Months	0	12	6
Three Months	0	[illegible]	6

TO THE COLONIES AND ABROAD.			
One Year	£1	5	0
Six Months	0	14	0
Three Months	0	7	0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs. 50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

Communications, Letters, &c., have been received from—

A.—Miss E. Austin, Clonakilty; Lieutenant Adolphe Abrahams, R.A.M.C., Aldershot.

B.—Messrs. Burroughs Wellcome and Co., Lond.; Bethnal Green Guardians, Lond., Clerk to the; Messrs. Bailey and Son, Lond.; Dr. A. E. Boycott, Radlett; Dr. B. N. Burjorjee, Rangoon; Mr. J. P. Buckley, Manchester; Mr. A. E. J. Barcroft, Maryborough; British American Tobacco Co., Lond.; Barnstaple, Medical Officer of Health of; Messrs. P. Blakiston's Son and Co., Philadelphia; Bolingbroke Hospital, Lond., Secretary of; Messrs. Birchall, Liverpool; The T. K. Bellis Turtle Co., Lond.; Messrs. Bishop, Lond.; Mr. W. Bentley, Lancaster; Mr. F. J. C. Broome, Harrogate; Mr. Harold Barwell, Lond.; Mr. C. Beesley, Exmouth; Dr. Y. Billing, Stockholm; Mr. Ernest Burchell, Brighton; Board of Education, Lond., Secretary of.

C.—Mr. Rolf Creasy, Wimereux; Mr. J. Jackson Clarke, Lond.; Messrs. E. Cook and Co., Lond.; Messrs. J. and A. An Investigation OF CERVICAL GLAND TUBERCULOSIS.

BY A. STANLEY GRIFFITH,
M.D. VICT., D.P.H.,
LATELY SCIENTIFIC INVESTIGATOR, ROYAL COMMISSION ON TUBERCULOSIS.

THIS investigation of cervical gland tuberculosis was undertaken as a result of the isolation of atypical strains of human and bovine tubercle bacilli from cases of lupus which had developed in the skin of the neck after excision or ulceration of tuberculous cervical glands. The object of the investigation was to ascertain whether or not tubercle bacilli raised from tuberculous cervical glands ever diverged from the standard in the same way as these lupus tubercle bacilli.

Up to the present time strains of tubercle bacilli with the aberrant characteristics pertaining to the majority of lupus tubercle bacilli have been demonstrated very infrequently in internal varieties of human tuberculosis or in animal tuberculosis. The clearest example of the occurrence of atypical tubercle bacilli of lupoid order in lesions of human tuberculosis other than those of the skin is recorded by Weber and Steffenhagen.[1] These observers isolated atypical bovine tubercle bacilli on three separate occasions from the tuberculous metacarpal bone of a child.* This result is of special interest, because two years previous to Weber and Steffenhagen's investigations Oehlecker[2] had isolated from the same lesion in this child a fully virulent bovine culture. This case and others which have yielded atypical tubercle bacilli will be referred to more particularly in a forthcoming report on lupus. Among animal species atypical tubercle bacilli apparently identical with some bovine lupus strains have been found occasionally in the tuberculous horse[3] and pig.[4]

As wider knowledge of the occurrence and distribution of variant strains is desirable, and is, indeed, essential to my study of the etiology of lupus, I am carrying out on an extended scale investigations of the biological characters of tubercle bacilli from as many varieties of human and animal tuberculosis as possible. Incidentally, these investigations are giving much needed information upon the relative prevalence of the different standard types of tubercle bacilli in tuberculous animals and man.

Examination of a series of cervical gland cases was considered of first importance because cervical gland tuberculosis is the only form of tuberculosis of which lupus has been observed to be a direct sequela. About 12 per cent. of the cases of lupus which I have examined have followed tuberculosis of the cervical glands, and in all but one of these cases the lupoid lesions have yielded atypical tubercle bacilli. There was presumption, therefore, that if atypical tubercle bacilli of lupus class are occurring at all commonly in regions of the human body other than the skin, the quest for these aberrant strains should be more successful in cervical glands than in other internal tissues of the human body.

Inquiry in this sense began in August, 1912. It is being continued, but I am reporting now on the cases collected up to July, 1914, because for several months after the outbreak of war there was intermission in the supply of material.

I wish here to express my grateful thanks to various surgeons and pathologists who have made this research possible by supplying me with material and with notes of the cases. In Table I. the source of each material is recorded, and for the purpose of future reference I have given also the initials and age of the patient and the date of receipt of the glands.

The material examined has been derived from widely separated centres of population, and, while probably not in consecutive series from any of the sources, has been forwarded without any kind of selection.

Description of Material.

The original material was obtained by surgical operation from 110 persons, including children, adolescents, and adults. The material was mainly lymphatic glands. In a few instances it was pus from an abscess or curettings from a tuberculous sinus in the neck.

The sets of lymphatic glands were of two sorts. The great majority of the sets contained definitely tuberculous glands, which were caseous or caseo-calcareous wholly or in part. The rest consisted of glands which were not apparently tuberculous; on section they were found to be composed of homogeneous hyperplasic glandular tissue, or they showed yellow suppurative foci. In two of the cases the glands were from the axilla, and in one from the femoral region. In all other instances they were from the neck.

Methods of Bacteriological Investigation.

The glandular material was reduced to a pulp in a mortar, emulsified with sterile physiological salt solution, and filtered through muslin. The emulsion was examined microscopically, and then used to inoculate intraperitoneally one or two guinea-pigs. An attempt was usually made to secure a culture direct from the original material. A guinea-pig was killed after the lapse of from three to five weeks, and cultures were made from it if tuberculosis had developed. Sometimes when the direct culture was assured a guinea-pig strain was dispensed with.

In a good number of instances the guinea-pig or guinea-pigs inoculated with original material did not develop tuberculosis, although that material was macroscopically tuberculous, and in many instances showed tubercle bacilli microscopically. Cultures were nevertheless made from the normal organs of many of these guinea-pigs, the glands adjacent to the omentum and the spleen being chosen for the cultural experiments. It is important when searching for atypical tubercle bacilli to make cultures from guinea-pigs which have been inoculated with material presumed to be tuberculous, though their tissues may appear at the post-mortem examination to be perfectly normal. I have on several occasions cultivated atypical tubercle bacilli from the tissues of guinea-pigs which presented no macroscopical lesions of tuberculosis four to six weeks after inoculation with lupus material.

All the cultures were raised upon egg medium without glycerine and subcultivated on pure bovine serum. Glycerine egg was frequently used for primary cultures, but solely for the purpose of getting early information as to the type of the tubercle bacillus. All tests, cultural and pathogenetic, were made with cultures which had been grown throughout on media free from glycerine.

---

* On a fourth occasion they obtained from the lesion a culture of typical bovine tubercle bacilli.

The differential media used have been glycerinated potato, glycerine serum, glycerine agar, and glycerine broth. The most reliable of these is, in my experience, glycerinated potato.

The comparative virulence of each culture has been tested on the rabbit by subcutaneous inoculation between the shoulders.

The subcutaneous method was chosen instead of the intravenous mainly because subcutaneous inoculation will bring out slight grades of attenuation in bovine tubercle bacilli which are not revealed by intravenous inoculation. The subcutaneous method also differentiates more clearly than the intravenous standard bovine tubercle bacilli from standard human tubercle bacilli which have displayed relatively high pathogenicity for the rabbit. Strains of human tubercle bacilli occasionally produce a good deal of tuberculosis in rabbits, and this tuberculosis, attributable either to higher virulence than is usual for human viruses or to specially susceptible rabbits, is apt to be more widespread and severe when the culture is inoculated intravenously than when it is inoculated subcutaneously.

The rabbits were inoculated with weighed quantities of moist growth from young serum cultures scraped from the surface of the serum with a platinum spatula and weighed directly without previous drying. The particular subcultures used were never more than 20 days old, usually 7 to 10, and except where repeat tests were necessary were in quite early generation, fourth to sixth.

The cultures which were bovine in cultural characters were tested on two or more rabbits, the dose in each case being 10 milligrammes; in a few instances the dose was a little more or a little less. The eugonic cultures were tested sometimes on two rabbits, sometimes on one only, and the dose given was often larger than 10 milligrammes. Rabbits were kept under observation until they died or until the experiment had lasted three or four months, when they were killed.

BACTERIOLOGICAL RESULTS.

The 110 cases with which I am dealing are divisible into three groups, comprising respectively 10, 29, and 71 individuals, as follows:—

Group 1.—Ten sets of lymphatic glands which were not macroscopically tuberculous did not produce tuberculosis in guinea-pigs. The glands in two of these sets contained small suppurative foci, and in the others were in a condition of hyperplasia. Microscopical examination of five and cultural experiments with four of the emulsions of the glands, including the two with purulent foci, yielded negative results. The patients from whom these glands were excised varied in age; five were under and five were over 12 years of age.

Group 2.—Lymphatic glands from 29 other patients also failed to produce tuberculosis in guinea-pigs. These glands were, however, definitely tuberculous to the naked eye and contained caseo-calcareous or softened caseous material or caseopus. In 15 cases tubercle bacilli were found in smear preparations of the emulsions used for inoculating the guinea-pigs; in 7 of these 15 emulsions tubercle bacilli were numerous or moderately numerous and were short and well-stained. Microscopical examination of 11 emulsions was negative, and of 3 was not made. Two of the cases were twice investigated, the interval between the examinations being four and a half and two and a half months, and on each occasion the result was negative. Fifty guinea-pigs in all were inoculated with the material from these 29 cases.

In order to ascertain whether the glands from these patients might not perhaps have been harbouring living tubercle bacilli, possessing so low an order of virulence as to be incapable of producing tuberculosis in the guinea-pig, many cultural experiments were made. Direct cultures were sown in 26 of the cases, and in 21 of these the culture tubes remained sterile, while in the remaining five they grew contaminating organisms. Cultures were also sown from the omental glands or from the spleens of 15 guinea-pigs, representing 13 of the cases; these experiments were likewise negative. The evidence suffices to show that there were in the material tested no living tubercle bacilli either of standard or of attenuated virulence.

I fully recognise that these negative results cannot be regarded as demonstrating necessarily the cure of the disease in the patient, but only that the tuberculous process was arrested in the particular glandular material used for experiment. Nevertheless they show conclusively that in glandular tuberculosis there is marked tendency to spontaneous cure of the disease. In this series of the sets of glands showing definite tuberculous lesions, 29 per cent. gave negative results in culture and in animal experiment. This tendency to spontaneous arrest of glandular tuberculosis should be remembered when estimating therapeutic effect of specific remedies in these conditions.

It is impossible to say what may have been the type of infection in these cases, but if, as seems probable (see below), the presence of numerous short tubercle bacilli is presumptive of bovine infection, 7 at least of the 29 cases were due to bovine tubercle bacilli.

There are many other instances recorded in which macroscopically tuberculous material has failed to produce tuberculosis in guinea-pigs.[5, 6] Several of the observers who have investigated cervical gland tuberculosis report such cases. Lewis[7] obtained negative results in 2 out of 17 cases of primary cervical gland tuberculosis. In both cases the microscopical examination showed the pathological picture of tuberculosis. Oehlecker[2] investigated cervical glands from 28 cases in which the clinical diagnosis of tuberculosis was indicated as probable, and in only 14 cases did the guinea-pigs inoculated develop tuberculosis. Oehlecker makes no statement with respect to the pathological condition of the glands from the 14 negative cases. Burckhardt[8] investigated 10 cases of cervical gland tuberculosis and found the material from one to be not infective for guinea-pigs. One of the 9 cases of cervical gland tuberculosis investigated by Cobbett for the Royal Commission on Tuberculosis, which yielded a bovine culture when first examined, gave negative results on two subsequent examinations.[5] In striking contrast to the above results are those of Mitchell.[9] This observer investigated 72 consecutive cases of cervical gland tuberculosis in children and did not obtain a single negative result.

Group 3.—In 71 of my 110 cases the original material produced tuberculosis in guinea-pigs, and cultures were obtained. Altogether 98 strains have been isolated, 33 directly and 65 through the guinea-pig.

The cultures from these 71 cases fall into two groups.

Eugonic Strains.

Thirty-seven of the cases yielded cultures which exhibited the cultural characteristics and rabbit pathogenicity of standard human tubercle bacilli. Each one of these strains produced luxuriant pigmented growths on serum and thick, creamy, wrinkled layers on glycerinated potato. Characteristic growths were also produced by each of the strains on one or other of the other glycerine media. Among the strains in this group there has been very little variation in degree of luxuriance. The virulence of one strain from each of the 37 cases has been tested on the rabbit by subcutaneous inoculation. Altogether 60 rabbits have been thus inoculated. In Table II. the details of these experiments are set out. The few rabbits which died prematurely are not included.

The pathogenic effects of these eugonic cultures have been very diverse, but the range of variation has not been wider than is usual in any large series of rabbits inoculated with standard human viruses. None of the rabbits died from tuberculosis, the period of observation being from three to four months. While in the great majority of the rabbits the tuberculosis produced was slight, in several it was of moderate and even of considerable severity.

Severe tuberculosis produced by human tubercle bacilli can as a rule be readily distinguished from the chronic forms of tuberculosis which sometimes follow subcutaneous inoculation of standard doses of bovine tubercle bacilli. Disseminated disease set up by human tubercle bacilli is generally limited to the lungs. There may be small tubercles in the kidneys, but these are usually few in number and retrogressive. The glands adjacent to the local lesion may show tuberculosis, but they are seldom extensively caseous. Distal lymphatic glands are almost invariably normal. Besides the difference in distribution of lesions there is difference also in the macroscopical appearance of the lesions, a difference which is at once apparent to those who have had some experience in the examination of experimentally tuberculous rabbits. Exceptions to this rule sometimes occur, and then it is necessary to isolate and test a culture from the suspicious lesion, for the original culture may have contained an admixture of bovine tubercle bacilli. In this series a culture was recovered from one of the most severely affected rabbits (No. 320). The recovered culture was eugonic and exhibited very low virulence for another rabbit, thus proving that the exceptionally severe disease in Rabbit 320 was due wholly to human tubercle bacilli.

It will be noted in Table II. that several cultures produced in the rabbit local tuberculosis only. Such limited pathogenic effect does not necessarily indicate an abnormally low grade of virulence of the particular cultures, for human viruses of proved standard virulence often produce in rabbits when inoculated subcutaneously no more than a local lesion. On account of this capacity of individual rabbits entirely to resist infection with standard human viruses the rabbit species is not a suitable one for estimating whether or not a culture of human type culturally is up to standard in virulence. In order to demonstrate attenuation in a human virus guinea-pigs (or monkeys) must be employed.

It is not, however, necessary systematically to test cultures of tuberculous viruses on the guinea-pig, because it is possible to judge from the results produced by the inoculation of original material whether the culture from that material is likely to show attenuation.

With one exception (exclusive of one case in which the guinea-pig died prematurely) the original material of the 37 human viruses produced typical tuberculosis in the guinea-pigs. The exception was Case 57, which produced in six weeks in one guinea-pig no tuberculosis, and in another caused tuberculosis limited to one inguinal gland. The culture raised from the latter guinea-pig was tested therefore in standard dose (0·1 mg.) on guinea-pigs as well as on rabbits. It produced in two guinea-pigs subcutaneously inoculated typical fatal general tuberculosis in 63 and 89 days. The slight effect in the original guinea-pig must be referred therefore to paucity of living tubercle bacilli in the emulsion and not to attenuation of virulence.

Dysgonic Strains.

From the remaining 34 of the 71 cases yielding cultures, the cultures isolated displayed less cultural luxuriance and higher virulence for the rabbit than those in the group just dealt with. The strains of these viruses have exhibited a wide range of variation in degree of luxuriance. In respect to 32 of the 34 viruses the range of cultural luxuriance corresponded exactly with that ascertained by the investigators of the Tuberculosis Commission for tubercle bacilli of bovine tuberculosis.

The two remaining strains have grown rather more luxuriantly than any strain of bovine origin which I have hitherto met with. The increased luxuriance was observed in primary culture on glycerine egg and in subculture on glycerine agar. On glycerine egg the colonies were as numerous as, and larger than on egg alone, but they were not pigmented (bovine tubercle bacilli as a rule grow very sparsely on glycerine egg in primary culture); on glycerine agar the growth ultimately formed was in places dense, wrinkled, and slightly pigmented, but the layer was not uniform and the rate of growth was slower than with human tubercle bacilli.

Similar relatively eugonic virulent strains have been isolated by Eastwood and F. Griffith from tuberculous children[6] and from the tuberculous lesions of swine.[4] The cultural characters of these two cervical gland strains were found to be stable after animal passage. Each strain was passed through the bodies of three rabbits in succession, and cultures from distal lesions of the last rabbit as well as from those of the two previous ones were identical in cultural character with the original culture. There was therefore no evidence of admixture of human tubercle bacilli.

The cultures from all these 34 cases proved highly virulent for rabbits and produced in them fatal general progressive tuberculosis identical in every respect with that produced after similar interval of time by tubercle bacilli of bovine tuberculosis.

None of the 71 viruses, whether of human or of bovine type culturally, has shown any evidence of attenuation. The culture from each virus was either a standard human culture or a standard bovine culture.

[The cultures from three of the cervical gland cases—viz., Nos. 53, 88, and 95—were isolated and tested (except the virulence test of Case 95 which was made by me) by Drs. Eastwood and F. Griffith. Two further cases, macroscopically tuberculous, investigated by them did not produce

TABLE I.—*List of Cases which yielded Cultures, and Summary of Results.*

No. of case.	Designation and date of virus.	Source of material.	Sex and age in years.	Macroscopical. Condition of glands.	Microscopical. Smear preparations of emulsions.	Derivation of cultures, direct or through G P.	Results in guinea-pigs inoculated with original material.	Classification of cultures.

Note.—* Those marked with an asterisk were killed. All the others died. G T = General tuberculosis. G T^1 = General submiliary tuberculosis of moderate severity. G T^2 = General tuberculosis severe in lungs only; kidneys only slightly affected, liver and spleen normal; popliteal glands contained caseous tubercles, but others, excluding those nearest local lesion which were extensively caseous, were normal. E G T^3 = Early general tuberculosis, liver peppered with minute grey foci. G T^4 = General tuberculosis of moderate severity only. G T^5 = General tuberculosis (cultures from the portal and popliteal glands of Rabbit 1407 resembled the original culture in cultural characters). G T^6 = General tuberculosis (cultures from the kidney and popliteal gland of Rabbit 1408 resembled the original culture). G T^7 = General tuberculosis (not quite of full severity). G T^8 = General tuberculosis moderate. Death from pseudo-tuberculosis of liver. G T^9 = General tuberculosis not of maximum severity.

tuberculosis in guinea-pigs nor yield cultures. I am indebted to them for giving me the details of their experiments and for allowing me to include these five cases in my series.]

(For details of the cases referred to above see Tables I., II., and III.)

Of the several observers who have made bacteriological investigation of cervical gland tuberculosis one only (Duval[10]) claims to have isolated atypical tubercle bacilli. Duval isolated cultures from four cases of cervical adenitis of an unusual clinical type. Three of his cultures are classified as atypical —respectively human, bovine, and avian—and the fourth as a standard human strain. His atypical cultures bear no resemblance, judging from the information given as to cultural characters and virulence, to any of my atypical lupus strains, nor indeed to any tubercle bacilli hitherto described. As Duval's results are exceptional and without confirmation it is unnecessary to refer to them more particularly here. The cultures isolated from cases of cervical gland tuberculosis by other investigators who have given details of their experiments are clearly either of standard human or of standard bovine type. Whether or not any of Mitchell's cervical gland cultures varied from the standard in respect of virulence I am not able to judge, as this author has not given any details of individual rabbit experiments.

Relation of Macroscopic Characters of the Glands and Numbers of Tubercle Bacilli present to the Type of Infection.

In each case the macroscopical appearances of the glands on section have been recorded with the object eventually of determining whether or not these presented differences corresponding to the type of infection. Careful comparison has not revealed any macroscopical character which is peculiar to one type of infection. On the other hand, microscopical examination would appear sometimes to yield evidence indicating type of infection. When there are numerous short well-stained tubercle bacilli the probability is that a bovine infection is being dealt with. In the series yielding cultures there were numerous or moderately numerous short tubercle bacilli in eight cases, and in each of these cases bovine tubercle bacilli were isolated. In Oehlecker's series[2] of 14 cases there were numerous short tubercle bacilli in the only cases (4) which yielded bovine cultures. Bovine infections, however, are not always associated with numerous tubercle bacilli in the lesions. Seventeen of the cases from which bovine tubercle bacilli were obtained in culture showed no, or extremely few, tubercle bacilli microscopically. In human infections tubercle bacilli are usually very scanty. In only 2 out of 33 "human" cases in which microscopical examinations were made were tubercle bacilli found in moderate numbers.

Clinical Aspects.

The clinical information with which I have been supplied contains some features of interest which are briefly detailed in the abstracts below.

CASE 2.—Aged 23. Bovine infection. History of seven or eight years' trouble with glands on both sides of neck and in one axilla. She had been operated on altogether six times by Mr. Thelwall Thomas and Mr. Kelly. She stated that she was very fond of cows' milk and always drank it unboiled. Teeth very carious.

CASE 4.—Aged 39. Human infection. Twelve years' history. She had had five operations, exacerbation leading to operation all following confinement. Of four children, one suffered from chest trouble, one from tuberculous wrist, and a third from glands in the neck.

CASE 14.—Aged 19. Bovine infection. Four months' history. She had been in the habit of drinking cows' milk unboiled and had several very carious teeth. There was a large mass of glands beneath the left sterno-mastoid. Two years after operation she was seen by Mr. Kelly, who found only one small gland low down in the neck—not worth operation.

CASE 24.—Aged 24. Human infection. Five years' history. Had had three operations.

CASE 46.—Aged 17. Human infection. Glands noticed only two months before operation. She had been under treatment for some time with well-marked signs of cavity in left apex.

CASE 47.—Aged 14. Bovine infection. Enlarged submental glands for some years, and abscesses had formed and burst three times.

CASE 48.—Aged 18. Bovine infection. Three years' history. Two operations.

CASE 62.—Aged 9. Human infection. Chronic enlargement of cervical and axillary glands, both sides, for two years. Had had three operations. Many carious teeth when first seen.

CASE 68.—Aged 8. Human infection. Case of old empyema. Axillary glands affected on side of operation for resection of rib.

CASE 74.—Aged 6/12. Bovine infection. There was also a tuberculous lesion of the hand.

CASE 77.—Aged 41. Bovine infection. Five years' history. There were enlarged glands in both posterior triangles and both tonsils were enlarged. He had been accustomed to drink unboiled cows' milk. Eleven months after operation he writes to say that his neck was fuller than ever of glands.

CASE 81.—Aged 9. Bovine infection. Child said not to have taken milk except in puddings. After the operation a small swelling appeared under the site of operation, but after a time this began slowly to dwindle and further operation was considered unnecessary. The general health of the child was good. There was no family history of tuberculosis.

CASE 86.—Aged 13. Bovine infection. About six weeks' history. Large mass of glands on left side of neck. Patient died at end of operation from heart failure. The post-mortem examination showed perihepatitis and perisplenitis, and greatly enlarged caseous mesenteric glands.

In a few other cases, both human and bovine, it has been ascertained that the operation was completely successful and that there had been no recurrence. Of 11 cases in which it was stated that there was no family history of tuberculosis, 3 yielded human tubercle bacilli and 8 bovine tubercle bacilli. Family history of tuberculosis was given in 2 cases; one of these was infected with human, the other with bovine tubercle bacilli.

Statistical Data.

For the purposes of this section I shall utilise only those cases which yielded cultures and which are believed to be primary in the cervical glands. Three of the 71 positive cases must therefore be excluded. One (No. 46) was a case of cervical adenitis which was probably secondary to tuberculous disease of the lungs. The other two (Nos. 68 and 90) were cases of tuberculosis of the axillary glands, the cervical glands being unaffected. There remain 68 cases of cervical gland tuberculosis, presumed to be primary in the cervical glands, of which 35 yielded cultures of human tubercle bacilli and 33 cultures of bovine tubercle bacilli. The case (No. 52) in which the femoral glands were the original material is included in the 68 cases, because the cervical glands were also tuberculous.

Table IV. shows the relative incidence of human and bovine infections at various age-periods in this series of 68 cases.

TABLE IV.

Age-periods.	Number infected with— Human T.B.	Number infected with— Bovine T.B.	T.B. dead in—
Under 5 years	1 (10·0%)	9 (90·0%)	6 (37·4%)
5 to 10 years	7 (39·9%)	11 (61·1%)	8 (30·7%)
10 to 15 years	8 (61·5%)	5 (38·5%)	5 (27·7%)
15 to 20 years	6 (60·0%)	4 (40·0%)	2 (16·6%)
20 and upwards ...	13 (76·5%)	4 (23·5%)	5 (22 7%)
Totals	35 (51·5%)	33 (48·5%)	26 + 3 in which age not stated (30%).

The proportion of bovine infections is highest in children under 5 years of age and lowest in adult life. The incidence on adults is not, however, unimportant. The percentage of adults over 20 years of age infected with bovine tubercle bacilli is in fact remarkably high, and is higher than has been recorded in any other series of cervical gland cases or in any other variety of tuberculosis in the adult.

In the next table (V.) the cases are analysed in accordance with the locality from which they were derived.

TABLE V.

H = Human infections. B = Bovine infections.

The figures are not large enough for comparative statistical purposes as between different centres of population, but set out in the above manner they show quite clearly that none of the localities investigated enjoys freedom from risk of infection with bovine tubercle bacilli.

More reliable percentage figures are obtained by combining the cases into three groups, to represent respectively London and district, the rest of England, and Scotland. These figures are exhibited in Table VI., and for purposes of comparison the principal American and German figures, the total cases reported in all countries down to July, 1912, and Mitchell's figures for Edinburgh are set out in similar fashion.

The American, German, and combined figures are taken from the tables compiled by Park and Krumwiede.[11]

The table shows that in my series the proportion of persons infected with bovine tubercle bacilli in London and district and the rest of England is much about the same, while in Scotland the proportion is much higher. The Scotch figures afford corroboration of the conclusion arrived at by Mitchell as a result of his investigations of cervical gland tuberculosis that infections with bovine tubercle bacilli in this variety of tuberculosis are very prevalent in Edinburgh. Mitchell's inquiries were confined to persons aged 12 years and under. My figures suggest the importance of making in Scotland a more extended investigation of cervical gland tuberculosis in adolescents and adults.

* 5 to 16 years. † 16 and upwards. ‡ 5 to 12 years.

The proportion of bovine infections in cervical gland tuberculosis in England, while less than that in Scotland, is higher than it is in other countries. Of the four countries for which there are separate data in Table VI. Germany gives the lowest percentages of bovine infections. There is not much difference between the English and American percentage figures (respectively 55·5 and 51·7) for persons under 15 years of age, but for persons over 15 years of age the proportion of cases in which the infection was "bovine" is considerably lower in America than in England.

The greater part of the work here reported on was done during my tenure of one of the scholarships of the Grocers' Company and with funds supplied partly by the Grocers' Company and partly by Professor G. Sims Woodhead. In recent months the expenses of the inquiry have been borne by the Medical Research Committee. I desire to acknowledge my indebtedness to these sources for the means, and to Professor Woodhead for the use of the Pathological Department of the Field Laboratories, University of Cambridge, to carry out the bacteriological work.

ROYAL NATIONAL SANATORIUM, BOURNEMOUTH.—The committee of management of this institution have under consideration a scheme for forming a "sanatorium colony" in conjunction with the present institution. It is proposed that a piece of land, about seven or eight miles from Bournemouth, should be acquired on which could be erected simple buildings to accommodate 40 patients. To this colony could be drafted all patients who, after careful selection, were considered suitable for employment on various grades of work. The advantage of the scheme would be the separation of advanced cases from those only slightly affected. The cost of the scheme will be between £3000 and £5000, but this is less than the accumulated surplus income of the sanatorium during the past three years. The result of the deliberations of the committee of management will be submitted to a special meeting of the governors.

NOTES ON RHEUMATISM IN CHILDREN.[1]

By MARY H. WILLIAMS, M.B., B.S. Lond.,
D.P.H. Camb.,
SENIOR MEDICAL INSPECTOR OF SCHOOLS FOR WORCESTERSHIRE.

It is hardly possible to read a medical journal of any description without coming across an article on some form of tuberculosis, and recently legislation has even more strongly called attention to its importance. Mothers are willing to take much trouble for their children if one tells them the child is tuberculous, so thoroughly are they imbued with terror of this disease. But I am inclined to believe that in England as much, or more, misery is caused by the disease we call rheumatism, and each year I live I find cause to study some fresh manifestation of this widespread disease.

The laity commonly regard rheumatism as a disease of the elderly, and believe that its chief harm lies in the pain it causes. I believe that it is a disease which almost always begins in early childhood, and that in its crippling effects it is second to none. It is responsible for a large amount of heart disease and for an infinitely larger number of cases of ill-health which are frequently labelled "debility." The common view as regards the sequence of events appears to be that "growing pains" come before the heart is affected. Dr. R. Hutchison writes[2]: "If they [the growing pains] are neglected the child ...... may very easily slide into endocarditis," but I hope to show that the germ commonly first attacks the heart and only later causes symptoms in muscles and fasciæ.

The little I know about rheumatism in children has been learnt almost entirely in my work in the schools, for, with the exception of Dr. F. J. Poynton's book, there is not much to be learnt about it from current literature. So I have had to formulate my own views, and hence must ask for indulgence if I differ from any of my audience. My views have developed as the result of watching given children for long periods, 5, 6, 7, or even more years, and noting how one condition precedes, and passes into, another.

I started school work in 1904, believing that there was very little rheumatism in children. The first method I used to ascertain if a child was rheumatic was to ask if he ever had "growing pains," and I was absolutely startled to find how many children gave a definite affirmative answer to the direct question. A few had volunteered this information before I started asking directly. Then came the question as to whether "growing pains" always connote rheumatism, and this forces me to what I should like to avoid—a definition. So I will shortly define rheumatism as the disease due to an infection with a specific micrococcus, probably that described by Poynton and Paine or one closely related to it. The syndrome of rheumatism includes symptoms due to lesions in the musculature and valves of the heart, pains in joints and muscles, abnormal excitability of nerves and brain shown in some cases by actual chorea, anæmia, with continued pyrexia. I regard malignant endocarditis as being commonly a severe form of septicæmic rheumatism, though quite recognising that in a few cases other germs are the primary cause.

Taking this definition to work upon, I believe that in young girls aching of the legs, which occurs both by night and by day, is almost always due to rheumatism. In boys I am inclined to think that a certain amount of aching can be caused by strenuous games even without rheumatism. But true rheumatic "growing pains" are generally worse after exercise, and at first may occur *only* after exercise. In many cases they are worse at night, and in such cases the diagnosis is at once clear. Also if they occur only, or chiefly, in wet weather they are due to the rheumatic toxin. Aching of the legs due to syphilis may occur, but I do not think that it is frequent in children. The aching which occurs during or before menstruation also needs mention, but can easily be differentiated by a few questions. Apart from these forms of aching there also needs to be differentiated a somewhat uncommon condition, aching of the joints or muscles due to the tubercular toxin, a tuberculous arthritis. So-called arthritis sicca, a dry form of tuberculous arthritis, has long been recognised, and this is sometimes, though by no means always, accompanied by pain. This condition is most easily recognised in the shoulder, because when auscultating the back one hears a dry crepitant sound, and on placing a hand on the shoulder one feels a creaking sensation. The creaking is produced in the muscle and can be lessened, or obliterated, by the arm being drawn backwards. Later there may be grating in the joint, but the early sounds are, I believe, distinct in origin. I believe this condition is practically always due to a tuberculous infection and not a rheumatic one.

The "growing pains" are the symptom most commonly recognised as due to rheumatism, but they are by no means the earliest or the most important. The typically rheumatic child can be differentiated by the age of 5, and, for all I know, far earlier. The reason why I name this age is because I see far more children at 5 than earlier, and I also find that the examination of children grows gradually more and more difficult as we come to deal with them at the earlier ages. At 5, such a child is often well nourished, perhaps somewhat thin, but one in regard to whom no complaint is made by the mother unless she says either that he is nervous or is "mincing" with his food. On examination, one obtains a history of rheumatism in the relations. When one takes the child on one's knee in order to count the pulse, one at once notices that he is not for one moment at rest, some part of his body is in incessant movement. The hand is not kept still long enough to make it possible to count the pulse for 60 seconds consecutively, one has to count it in successive quarter minutes The hand is constantly making little, quick, jerky movements. And, without questioning, the parent will often remark that he is never still. Teachers complain that he fidgets. Then, on counting the pulse, one finds that it is above the rate of the child who has not acquired the rheumatic infection. So little work has been done on the pulse-rate that I carefully avoid the expression "the normal rate," but I have now many hundreds of records of five-year old children, and the children we are considering have a pulse-rate above that of tuberculous children, the rate often reaching 100 or over. Lately I have been seeing, for the second or third time, older children, in regard to whom the only note of abnormality made when they were first examined at 5 years was "tachycardia," and practically all of these are now definitely rheumatic. Moreover, this pulse-rate persists for years, and is not definitely higher on first taking. The variation is often extraordinarily small. I have notes where the variation shown over several years is only two or three beats per minute. In addition to the quick pulse-rate, such children frequently have continued pyrexia, with temperatures ranging from 99·4° to 100·4° F. It will be argued that this is due to "nervousness," but I now have records of some 5000 temperatures, and, as a rule, the second time of taking it is practically the same as the first. If the raised temperature were due to nervousness the second temperature would be lower than the first. This raised temperature persists for years throughout school life and the small amount of variation is remarkable. In work undertaken in collaboration with Professor Karl Pearson and Miss Julia Bell[3] we showed that this raised temperature is not merely due to age. Control takings were made at several public schools, both for boys and girls, and these showed that children of richer parents have not such raised temperatures.

[2] Lectures on Diseases of Children, 1913, p. 170

In a few cases, even as early as 5 years of age, growing pains are already present, but I regard these cases as of a more severe type than when the only signs are pyrexia, quick pulse, and nervousness. On inspection the heart's impulse is often widely visible, and on palpation it gives to the fingers a sensation of fluttering. On auscultation one finds that the common trouble at the bases of the lungs (which occurs at an earlier age and which I believe to be of tuberculous origin) has nearly cleared up, and often far more completely cleared up than in a child of a non-rheumatic family. There may be high-pitched expiration or harsh breathing. The apex beat may be outside the nipple line, which is not the case in non-rheumatic children. At a recent discussion at which various cardiac specialists took part, the ordinary position of the apex beat in children was discussed, and opinions varied as to whether it is within, or without, the nipple line. I think that the difficulty came from the fact that in rheumatic children it is often in or outside the nipple line, and there are so many such children in any hospital clinic, recognised or unrecognised, that statistics based on such figures, obtained without definite exclusion of rheumatic children, ought not to be regarded as representing facts concerning healthy children.

In some cases the cardiac sounds are altered, a muffling being perhaps the most common change, but I do not often hear bruits indicating actual valvular roughening. At this stage I think that the change consists in a weakening of the myocardium, which I believe to be toxic, but which it is possible may some day be shown to be due to actual rheumatic nodules in the musculature of the heart. This is the stage when, I believe, further development of rheumatism can be prevented, and, if this occurs, little permanent change remains. But, unfortunately, except in the children of the rich, the existence of the disease is not recognised at this age and hence the later stages are so appallingly frequent.

At some age between 5 and 12, a common symptom is abdominal pain, and also, I believe, attacks of appendicitis, almost always labelled "bilious attacks." In 3 out of 7 attacks, of which I have notes, there was a definite rigidity over the appendix. In 8 patients whom I questioned directly after they had been operated upon for appendicitis, I obtained, without leading questions, a history of bilious attacks in 7. I do not mean to suggest that the rheumatic germ is responsible for all attacks of appendicitis, but I think that "bilious attacks" in children generally precede recognised appendicitis, that they are, in reality, frequently slight attacks of appendicitis, and that both bilious attacks and appendicitis are more frequent in rheumatic children, or in persons with a rheumatic family history; and that it is at least possible that the same germ which causes the rheumatic nodules in the valves of the heart causes similar nodules in the region of the appendix. I gradually became so convinced by the cases I saw of some connexion between rheumatism and appendicitis that it has been a great pleasure to me to realise that other workers are also studying the subject from this aspect. In Poynton and Paine's book[4] an account is given of appendicitis produced in rabbits by the intravenous inoculation of diplococci grown from a case which was clinically rheumatic fever. The rabbits used were young, and the diplococci were recovered from the joints, the heart blood, and the peritoneal fluid.[5] In one case recorded, a patient with appendicitis had also some inflammation of a tonsil, and from both a diplococcus was obtained which appeared microscopically and culturally the same, and which gave rise to arthritis when injected into young rabbits.

That children in rheumatic families have frequent sore throats is well known, and many cases in consequence undergo operation on the tonsils. I should like to take the opportunity of protesting against enucleation of the tonsils. It is often said that guillotining is no good, for the condition recurs. For several years I have kept detailed notes of all the operation cases I have seen, most of them done by general practitioners, and I find that in the majority of cases, *if the operation is not done at too early an age*, the result is a cure; and I think whether it is or not, one has no right to remove organs until one is sure that their influence for good is less potent than their influence for evil. It is possible that the rheumatic germ grows in the tonsils, but, on the other hand, it has been argued[6] that the tonsils have a protective function. They may thus act as a barrier against rheumatism, and may only fail in this duty under repeated and severe attacks of the germ. If so, I think some portion should be left for defensive purposes.

The question as to whether chorea is or is not part of the rheumatic syndrome has been debated so many times, and the positive evidence is so great, that I think I need do no more than express my adherence to this view. If anyone is interested in working at the question further, I would be happy to afford facilities of studying my records of some thousands of cases which I regard as rheumatic, in regard to each of which is recorded the exact evidence on which the view was formed, and among the data would be found cases of chorea. I have no case of chorea as occurring in any but a rheumatic child, and I dissent from the view urged by Professor Poncet that the ordinary type of chorea is often caused by the tubercle bacillus.[7]

[5] Loc. cit., p. 374.

[6] Digby: THE LANCET, Jan. 20th, 1912, p. 160.

The mention of the tubercle bacillus brings me to a point at which I can state a theory which I have worked out—viz., that rheumatism and pulmonary tuberculosis are antagonistic and not active at the same time in the same child. Predisposition to rheumatism is strongly hereditary, and the figure based on my investigations has worked out at 0·46. I may say that the figure[8] for inheritance of stature is 0·51, for length of arm 0·5, and for insanity 0·47. Hence our heredity figure for rheumatism is strictly comparable to figures for other inherited characteristics. But, in addition, rheumatism in the parent appears to protect the child in a definite degree from pulmonary tuberculosis.[9] The antagonism between rheumatism and pulmonary tuberculosis has also been noticed by Sir Dyce Duckworth[10] and by Dr. R. H. Miller,[11] of Paddington Green Children's Hospital, and I have now thousands of records supporting this view.

But to come back to our rheumatic boy. By the time he is 12 he is probably in fair health but too thin, perhaps pale, and too easily out of breath. Also football or long walks cause leg aching. The apex beat is very likely to be found in or outside the nipple line. The impulse is very visible, far too diffuse, and on feeling it one is sensible of a kind of fluttering sensation. There may be a definite bruit with unmistakable involvement of the mitral valve. For many years I worried myself because at hospital it always seemed to me that everybody heard murmurs before I did, and I feared that I missed important lesions. Later, I had opportunities of comparing what I heard with what was heard by skilled auscultators, and so gradually learnt to know more. But for the consolation of any of the younger practitioners who may still feel as I did, I would say that, in children, not being able to hear murmurs does not matter. If there is enough wrong to need any degree of care the fact will be learnt more surely by the use of eyes and fingers than by the aid of the stethoscope. And if we trust more to our eyes and our fingers we shall, I hope, soon cease to talk of "functional" disease of the heart. The only definition of "functional" disease of the heart which I am willing to accept is the following: "A disease whose pathology I have not yet ascertained." The fact that the conditions, possibly the murmurs, in a child's heart are constantly changing is no reason for calling it "functional." If a sound is present one day and not the next it probably shows exhaustion of the muscle or activity of the rheumatic germ. So long as we call disease "functional" the inference is that it does not matter.

The sooner that we recognise that heart disease in a child is practically always due to rheumatism the sooner we shall get sufficient care taken to prevent the condition getting worse. In many congenital cases also I have obtained so strong a rheumatic family history, including disease in the mother, that I believe that here, also, rheumatism is often responsible.

Rheumatism is one of the commonest diseases of children and the most crippling in later life. But the disease does not now figure among those scheduled by the Board of Education, in spite of repeated attention being drawn to it by many doctors working in the schools. Heart disease is in the schedule, but not the disease of which heart disease is only a prominent symptom.

It does not yet appear to be sufficiently recognised that the rheumatic toxin is as capable of causing anæmia as the germ of tubercle or syphilis, and that in young people it is one of the commonest causes. In a recent interesting work, when writing of the anæmia of adolescence[12] Dr. Stacey Wilson separates "the anæmia definitely secondary to diseases such as phthisis and chronic nephritis" from "those which occur in the simple anæmia of adolescence" because "the cardiac phenomena are usually different." But I am gradually becoming convinced that the primary cause of many such "simple anæmias" is the continuous action during the years of childhood and adolescence of small doses of the rheumatic toxin, and environmental conditions supposed to be responsible for these anæmias are merely the causes which so increase the action of the toxin that symptoms are produced.

So far I have said nothing of treatment, and in regard to this matter I much hope to learn from those who have more practical experience of it than I. To my mind the riddle is unanswerable. The large proportion of the children in our schools have constant pyrexia; in rheumatic cases it is due to the rheumatic toxin, which at this age acts mainly on the heart. The first order I should like to give is, "Rest"; the second is, "Keep warm and dry"; and the third, "Good food." Yet I am in doubt which order is most hopeless.

The law compels the children of the poor to attend school in all weathers unless they can be proved to be definitely ill. Many of the country children have to walk two or three miles over fields or along wet muddy lanes, and then sit in cold schoolrooms. The cost of flannel makes the desirable form of clothing almost out of reach, and the small knowledge of cooking possessed by the women makes nourishing food a rarity. The wonder to me is not that a large number of our adults end their lives crippled with rheumatism, and a further large number die from heart disease, but that any of the poor escape the disease. I believe that we have something to thank tuberculosis for in that it renders some families more resistant to that disease which I consider the more deadly.

As regards the distribution of rheumatism, my figures show that rheumatism (as distinct from rheumatic fever) is more common in rural districts. So far as rheumatic fever goes, I have not found a greater frequency in urban than in rural areas.

When writing of valvular disease due to rheumatic fever, Dr. Harrison says[13]: "There is a special tendency to valvular disease in towns," and I have wondered if the frequency of slight rheumatism in children in the country districts is the *cause* of the comparative rarity of rheumatic fever in adults—i.e., is the early rheumatism an immunising process which protects from the more dangerous effects in the majority of cases? We often see it debated why mitral disease is so rarely found in post-mortem examinations on those dying from pulmonary tuberculosis. But if rheumatism and pulmonary tuberculosis are antagonistic, and mitral disease is generally due to rheumatism, then this absence of mitral disease would be bound to occur.

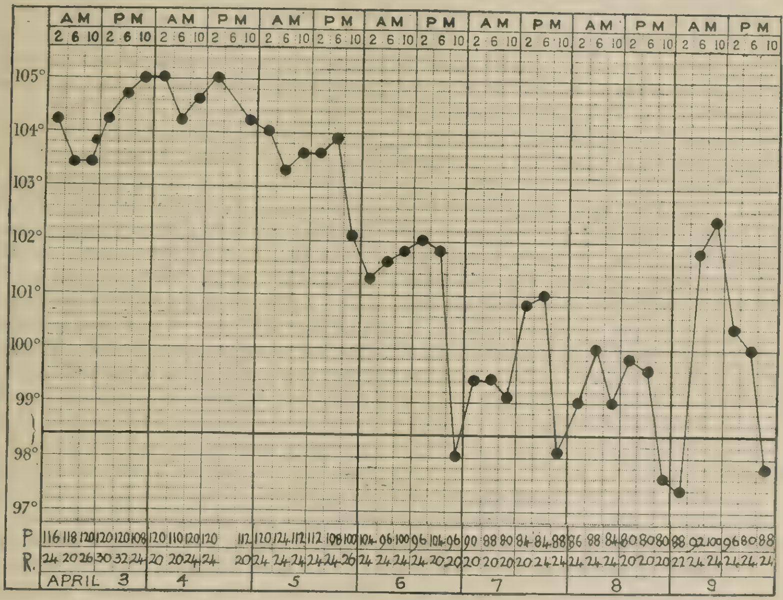
A CASE OF TETRAGENUS SEPTICÆMIA.

By HENRY ROBINSON, M.A., M.D. CANTAB.,
TEMPORARY LIEUTENANT, R.A.M.C.

A PRIVATE soldier of three years' service and 23 years of age was admitted to hospital on March 18th, 1915, complaining of pain in the feet of about six days' duration, with steadily increasing malaise, weakness, and anorexia. He had also a slight headache and a very slight cough. There had been some abdominal pain at the commencement of the illness, but this passed off before the man came under observation. On admission he was constipated, as is not unusual in men who have been a long journey on an ambulance train. He had not vomited, and there had been no nose-bleeding or sore-throat.

The only account of previous illness was a fever of some kind in India about a year before. The patient had never had rheumatism. He had been three times inoculated against enteric fever, the last time nearly a year previously.



Four-hour chart from April 2nd to April 9th.

On admission he looked fairly comfortable; not flushed; no herpes. He was rather deaf, and in view of a subsequent occurrence it is regrettable that no inspection of the ears was made. The tongue was red at the edges and furred in the centre. Temperature 103°F. The pulse-rate was 120 on admission, but it dropped soon afterwards to under 100; regular, low tension; skin moist, no rheumatic smell.

On examination nothing abnormal was found in the lungs. The heart's apex was just internal to the nipple in the fifth interspace. A soft blowing apical murmur was present; heard also at the basal region. There was no abdominal distension, gurgling, tenderness, or rigidity; no spots. The spleen was doubtfully palpable. There was no swelling or redness of the feet, though they were tender when handled. A diagnosis of acute rheumatism was made, and 20-grain doses of salicylate of soda with equal amounts of bicarbonate were given four-hourly, together with a brisk purge. On the off-chance of the case being one of enteric fever blood was withdrawn from a vein for cultivation. It was submitted to Lieutenant M. K. Acheson, R.A.M.C., bacteriologist, who found it sterile.

Under treatment the temperature fell rapidly, and became absolutely normal after six days. On March 22nd the man was much better in every way, and it is noted that the apical first sound was then almost normal, but still slightly impure. On the 26th the murmur was once more in evidence, though in other ways the patient had improved. On the following day salicylate treatment was discontinued altogether; the dosage had already been cut down as the symptoms ameliorated. The diet was cautiously advanced and absolute recumbency was maintained. On March 31st there was a slight nocturnal rise of temperature, and next morning a sudden return of pain in the legs and malaise occurred, together with a temperature of over 103°. Soon afterwards a condition of apathy almost verging on coma set in. There was no swelling or redness of the joints. Large doses of salicylate were once more exhibited, but this time without the slightest effect. The cardiac murmur was still present. On April 3rd the man complained of pains in the ankles, shoulders, and spine, but nothing abnormal was detected on examination of those regions. The temperature was 104°, the pulse-rate was 128, and the cardiac murmur had entirely disappeared. No petechiæ or abscesses were present. A diagnosis of infective endocarditis was arrived at; a further sample of blood was taken for culture and the salicylate was discontinued.

On the following day (April 4th) the patient, who had originally been admitted into a surgical ward, was transferred to the medical division of the hospital, and until my own transfer about three weeks later I lost direct touch with him. During this time he was under the care of Lieutenant A. T. Todd, R.A.M.C., with whom I saw the man occasionally in consultation. The case notes were carried on by Lieutenant Todd, and I am indebted to him for the particulars of this part of the illness.

On April 4th, on taking over the case, Lieutenant Todd's notes state that the man was slightly cyanosed. He complained chiefly of pain over the pericardium and base of the left lung. A double mitral murmur was heard at the apex, which was tender. A cough began on this day, and patches of broncho-pneumonia were found in both lungs. The spleen was enlarged. Pulse 120, very weak and dicrotic; temperature 105°. The patient was very delirious. Quinine sulphate in heroic doses was ordered. On the 5th there was a distinct improvement. The cardiac murmurs were unchanged, but the temperature was lower, the pulse less weak and dicrotic, and the cyanosis had disappeared. On the 6th the improvement continued, though there was still some nocturnal delirium. On the 7th he felt better, though the pulse tension was still very low; there was copious mucopurulent expectoration. Lieutenant Acheson reported that the blood contained the micrococcus tetragenus. By the 10th the temperature was normal and the præcordial pain was much less; there was some blood mixed with the mucopurulent expectoration. On the 14th a general quinine rash was observed, and also a purulent discharge from the right middle ear, but the general condition was much improved and the cardiac murmurs were no longer heard. On the 16th pleuritic pain was present on the left side, and examination showed a small patch of consolidation, with crepitations and blood-stained sputum and a temperature of 100°. Quinine was once more freely pushed. This attack soon subsided, though the sputum was still stained six days later, when the patient was feeling much better and asking for food.

About this time Lieutenant Todd left for the front, and the patient came once more under my care. I found the heart sounds normal, the cough practically gone, and, apart from weakness, hardly any morbid signs except aural discharge. From this pus Lieutenant Acheson had cultivated a coccus which grew both in pairs and in fours. He was inclined to regard it as the same organism (tetragenus) as that which he had already recovered from the blood. On April 27th the patient developed slight femoral thrombosis on the left side. On May 5th it is noted that the ear had ceased to discharge and the heart sounds were normal, but there was still tenderness, and a hard cord was still palpable along the line of the femoral vein. A few days later the patient was transferred convalescent to a hospital ship.

The exact sequence of events in the pathology of this case is not absolutely certain. The original attack seemed to respond satisfactorily, though not immediately, to salicylate treatment. It may have been true acute rheumatism; alternatively it is arguable that it was really even then a tetragenus infection. When the first relapse took place the diagnosis of infective endocarditis supervening on a simpler rheumatic lesion seemed inevitable, and a bad prognosis was formed. The temperature chart alone would suggest a pneumonia, but it was only after two or three days of high pyrexia that cough and pulmonary signs developed. The middle-ear abscess may have been pyæmic in nature. It would have been of great advantage in deciding this point if the ears had been examined for old perforations on the patient's first admission.

Fortunately Lieutenant Todd had had experience of tetragenus pneumonia at the Royal Victoria Hospital for Sick Children, Edinburgh, where he had found quinine of great value. He had already adopted the same drug in this case before the bacteriological finding was known, and in view of the upshot it would be certainly worth while to treat any future case in the same way. Such textbooks of bacteriology as are available on the spot here are practically silent on the pathogenicity to man of the micrococcus tetragenus, and I was very fortunate to find in Lieutenant Todd a colleague with first-hand knowledge of the tetragenus pneumonia, which occasionally attacks children. Even he, however, had not met with a case of blood infection by this organism, so I have thought it worth while to place this case on record in spite of the fact that I am not in a position to give any references to similar cases that may have already been published.

I tender thanks to Lieutenant Todd and Lieutenant Acheson for their valuable help.

NASAL FLAP AND MODIFIED LANGENBECK OPERATIONS FOR CLEFT PALATE.

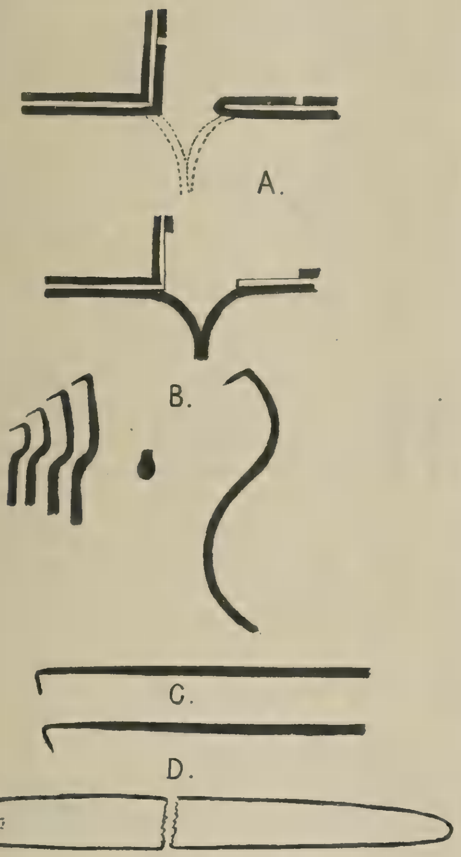
BY G. S. THOMPSON, F.R.C.S. ENG.

ONE of the commonest and most annoying sequelæ of palate operations is the yielding of the line of union, partly from infection, more especially when tension is present, the absolute and universal elimination of tension still being a desideratum that has not yet been realised. By the following operation and technique this defect, particularly in the case of the hard palate, which is the chief offender, can, I think, be satisfactorily overcome in most or all cases. The principle of the operation is the elimination of tension, the reduction of trauma and interference with the blood-supply by the use of flaps obtained from the upper aspects of hard and soft palates, which being turned down into the mouth are united in a V-shaped manner. The raw surfaces of the flaps are apposed, as well as the line of section, thus affording a firmer and more certain bond, and therefore reducing the likelihood of mal- or non-union. A graduated series of knives and raspatories make any width of flap desired to be obtained; moreover, the width is thereby maintained the same throughout. The width of flap required having been decided on the requisite knife is inserted from the mouth through the cleft, then drawn with some force through the muco-periosteum, from end to end, the shaft of the knife being kept in contact with the bony edge of the cleft. The flap thus demarcated is then separated from the nasal surface of the hard palate, drawn inwards and turned down through the cleft into the mouth. The raw surfaces are apposed and united by a few vertically placed mattress sutures and the edge by a continuous catgut suture, the mattress sutures being placed vertically and not horizontally so as not to interfere with the transversely disposed blood-supply to the flap margins. By this device the lateral paradontal incision and separation of palatal muco-periosteum with its involved danger to the blood-supply, not to mention trauma, can be avoided; but for those surgeons who prefer to combine this, the muco-periosteum may be raised through a small puncture near the teeth. So much for the hard palate.

With regard to the soft palate, at the present time a very necessary but most defective step in these operations is the inevitable section of the tensor, and even levator, palati as well as the separation of the nasal portion of the soft from the hard palate, these two factors probably accounting for some or most of the common after-trouble with phonation. I have endeavoured to overcome this cardinal defect in the case of the soft palate in the same way as the hard, but whether as successfully it is at present rather too early to state owing to small experience of these operations. To this end the tip of the soft palate is drawn forward on to the hard, and a longitudinal incision is made on its naso-pharyngeal surface through half its thickness this incision follows the same line as the intranasal section for the hard palate. The flap so marked out is raised, turned into the cleft and down into the mouth, so that later what was part of the upper surface will face the tongue. The two palatal incisions are then united at the posterior edge of the hard palate by curved scissors, thereby giving one long incision and flap from the upper aspect of hard and soft palates from end to end of the fissure.

By this operation I think it can be claimed that the palatal blood-supply is not impaired as is the case with the lateral section method; that important phonatory muscles are scarcely interfered with; that tension is obviated; and that apposing surfaces, more promising of union than edges, are obtained. And although the involved surfaces may be only half the thickness of the ordinary ones, yet this is more than compensated for by the fact that the arteries of supply are all intact, no tension prevails, and the gross trauma to the parts from the ordinary operation is avoided, all of which advantages favour union.

The diagrammatic illustration renders clear the method (A). Should the septum reach the palate the flap on that side is obtained therefrom. B shows the graduated knives and raspatory in profile, with screw disc on the latter for varying and maintaining the distance from the blade so as to render it adaptable for any width of flap. C indicates the knife and raspatory required for the septum, whilst D is the universal handle. The shape and size of the blade of knives and raspatories are also indicated, the knife having a cutting edge all round. The shafts are about 3 inches long, the handle 6 inches.



I would commend this nasal-flap operation to surgeons, particularly in the case of the hard palate which gives the chief trouble. The operation, if desired, can be performed in two stages.

Diphtheria at Larbert.—A serious outbreak of diphtheria has occurred at Larbert, Stirlingshire, and the central school has been closed.

COMPLETE HEART-BLOCK WITH HIGHER VENTRICULAR THAN AURICULAR RATE.

By EDGAR LEA, M.D. Vict., M.R.C.P. Lond.,
HONORARY PHYSICIAN, ANCOATS HOSPITAL, MANCHESTER.

A case of complete heart-block is here reported which presented the following unusual features: 1. An abnormally high and persistent idioventricular rate of 50 to 60 beats per minute, with occasional irregularity of rhythm not wholly due to premature ventricular contractions. 2. A period of sinal bradycardia of frequency 51, during which time the ventricular rate exceeded this. 3. Auricular tachycardia of frequency 200 per minute following the injection of 1/50 gr. atropine sulphate. 4. An unusual relationship between the auricular and ventricular beats during an apparent 3–1 block.

Clinical Description.

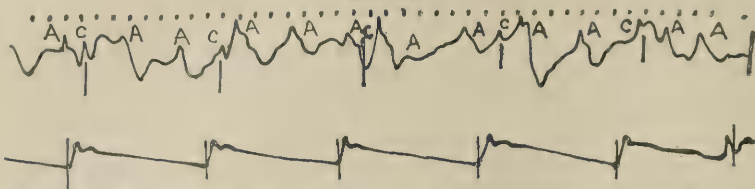
The patient, a man aged 38, was admitted into hospital under my care on Sept. 24th, 1913, having suffered recently from fits and dyspnœa. The family history was good. He was a married man with children. As to past history and habits, he had always had good health; no serious illness. He was a total abstainer and a non-smoker. His work had been healthy but laborious. No rheumatism; syphilis denied.

Present illness.—He was quite well up to a month before admission. When going for a walk one afternoon he suddenly lost consciousness and fell down. He regained consciousness, so his friend who was with him told him, in about a minute, and walked home. Another fit occurred at 11.30 that night and another at 4 o'clock the following morning. The next day he had four more fits on his road home from work, falling in the road each time. His doctor saw him that day. For the next three weeks he remained at home. During this time he states that he had three or four fits daily. Since Sept. 21st the attacks had been slighter in severity.

Condition on admission (Sept. 24th).—The patient was a well-built man of more than average height. His complexion was sallow and he looked rather ill. He said that since June he had lost weight, "pounds and pounds." There was considerable œdema of the legs, and the abdomen was a little swollen and felt tight. On examination the pulse was slow, regular, and of good tension; frequency 35·5 per minute. There was fairly well-marked venous pulsation in the neck. Heart: No apex beat was visible; no thrill. The deep limits of cardiac dulness were as follows: right limit, 1¼ inches; left limit, 5 inches from mid-sternal line; upper limit, third rib. On auscultation there was heard at the apex and at the lower end of the sternum a well-defined but not loud systolic murmur which replaced the first sound. The second sound was normal at all areas. At the base of the heart the sounds were less definite, but the impression was conveyed of intermediate, slighter sounds, probably of auricular origin, occurring between the ventricular contractions. The lungs were normal. Nervous system normal. The patient was intelligent and of a sanguine temperament. The liver was slightly enlarged and rather tender. A trace of albumin in the urine. Blood pressure: arm, 130 mm.Hg; leg, 122 mm.Hg. At a later date Dr. W. J. S. Bythell's X ray report showed evidence of much enlargement and dilatation of the whole heart. The separate movements of auricles and ventricles could not be satisfactorily demonstrated.

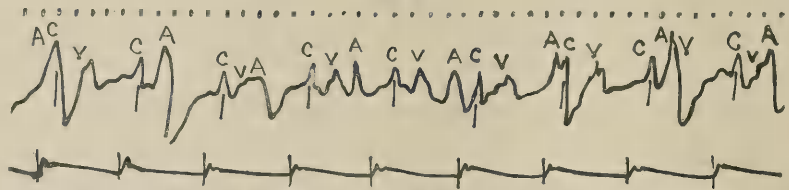
Progress and treatment.—On Sept. 25th the patient had a "fit" at 4 A.M. The nurse on duty stated that the pulse was absent during the fit (she had been warned to expect this feature); immediately afterwards the pulse rate was at 100. On Sept. 27th a second slight fit, not associated with loss of consciousness, occurred. The pulse was not stated to be stopped. This was the last fit which the patient had during his stay in hospital to Nov. 11th, 1913. On Sept. 29th potassium iodide, gr. 10 thrice daily, was prescribed, and this was continued till his discharge. During his stay in hospital his general condition improved. The œdema and the albuminuria quickly cleared up. There remained, however, throughout his stay, and subsequently, dyspnœa on exertion; and there occurred, following the first allowing of the patient up, a slight return of the œdema in the legs. This again subsided with rest. From Oct. 24th to Nov. 4th tincture of digitalis, ♏ 5 t.d.s., was given. This did not appear to have any influence upon the ventricular rhythm or upon the degree of block, which, as will be seen, remained complete throughout.

FIG. 1.



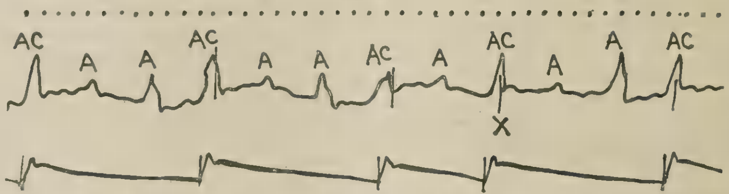
Tracing, Sept. 24th. Complete heart-block. Auricles 84 per minute; ventricles 35·2.

FIG. 2.



Tracing, Sept. 29th. Ventricular acceleration to 59; auricular slowing to 51 per minute.

FIG. 3.



Tracing, Oct. 2nd. Ventricular rate 30; auricular 90. Complete block still present. Note that at × there occurs a ventricular beat which is premature, but which coincides with a second auricular contraction. The auricular beat which precedes the synchronous A. and V. beat is larger than that which succeeds same. Though in this strip of tracing the auricle and ventricle seem throughout to fall together, this was not so when seen over longer periods.

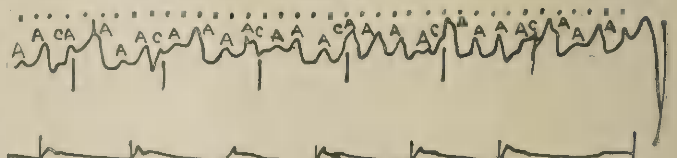
Polygraphic curves.—Complete heart-block was present throughout. On admission (Sept. 24th) the auricular rate was 84 and the ventricular 35·2 per minute. (Fig. 1.) Both rhythms were regular. Five days after admission, during which time the patient was not taking any drugs, the curve shown in Fig. 2 was gained. It shows that the ventricular rate had accelerated to 59 per minute, whilst the auricular rate had slowed to 51. Both rhythms continued regular. That the slow auricular rate was due to vagal influences was suggested by the fact that it was accelerated to 88 per minute after the hypodermic injection of atropine 1/60 gr. (20 minutes). This drug, however, neither on this occasion nor on any subsequent occasion had the slightest demonstrable effect in lessening the degree of A.-V. block. Whilst the atropine thus caused an auricular acceleration of 72·5 per cent., there was an associated ventricular decreased rate, a decrease of 15·7 per cent., for now the ventricular rate came down to 51 per minute. Three days afterwards (Oct. 1st) the auricular rate was at 96, the ventricular 34. The next day (Oct. 2nd) there appeared to be an exact 3–1 ratio: auricles 90, ventricles 30. Complete block, however, was still present. There was also a slight degree of ventricular arrhythmia present, although the auricular rhythm remained regular. Nor was such ventricular arrhythmia due merely to premature beats, a common finding, for it can be seen that the shortened ventricular cycles are due in nearly but not all instances to the ventricular contraction falling synchronously with an auricular contraction. (Fig. 3.) This event will be subsequently referred to. It may also be noted that the auricular beat which immediately succeeds such a synchronous contraction is smaller than that which precedes it, showing, presumably, a more forcible emptying of the auricle with the synchronous contractions. From about Oct. 10th the ventricle seemed to "settle down," as it were, to the rhythm which it maintained with but little variation during the rest of the patient's stay in hospital. Its frequency remained from 55 to 60 per minute. The auricular rate, too, maintained an average frequency of 88 per minute. The effect of vagus pressure in the neck was tried on Oct. 10th. No result followed right vagal pressure, but left vagal stimulation slowed the ventricular rate from 54 to 33 per minute. After this observation had been made 1/50 gr. atropine was injected. In 20 minutes it was found to have induced an unusually rapid auricular rate of 200 per minute. (Fig. 4.) The ventricle was not affected. No subjective symptoms were associated at any time with the vagaries of auricular and ventricular activities.

Some weeks after patient's discharge from hospital his doctor rang me up to say that the man had died suddenly whilst lifting some forms at a public institution, and he was good enough to forward to me the heart. The organ was large and of normal shape. There was a little atheroma around the aortic valvular orifice. In the interventricular septum, however, there was a dense, hard, yellowish thickening. This reached its maximal extent in the upper part, just in the region which the A.-V. bundle traversed. The nature was almost certainly syphilitic. The other valves and the myocardium were apparently healthy.

Remarks.

(*a*) *The ventricular rhythm.*—Mackenzie[9] states "there are now on record a number of cases in which the ventricular rate [in complete block] has been as high as 60." It is true that there have been several instances in which the idioventricular frequency has been stated to have been markedly accelerated for a brief period following a fit. In the case here recorded this fact was noted. And similar quickening of temporary character has been recorded by Hay and Moore,[7] Carrion,[1] probably Hoffmann,[8] also Earnshaw[12] and Laubry.[13] Two similar cases have been recorded by Dr. Byrom Bramwell in the *Edinburgh Medical Journal*, March, 1915. But in these instances such quickening has been associated with arrhythmia, and has often been due to frequently recurring ventricular extrasystoles. Again, experimental instances of increased idioventricular rate have been plentiful. Thus, Erlanger's and Blackman's experiments[4] showed that during complete block there occurred paroxysms of ventricular tachycardia at frequency 141, and in one instance even at 210 per minute. Lesser degrees of acceleration were noted by them following exercise, sympathetic stimulation,

FIG. 4.



Tracing, Oct. 10th. Twenty minutes after injection of atropine, 1/50 gr. Auricular rate 200 per minute; ventricular 53. Both rhythms regular.

and phasic variations related to Cheyne-Stokes respiration. Cullen and Tribe[3] found in the cat inconstant acceleration following accelerator stimulation. Increased ventricular rate has followed digitalis (v. Tabora,[11] Erlanger,[5] Hare[6]). When, however, we come to clinical instances, and if we confine attention to those cases where the acceleration is due to causes other than occasional and irresponsible extrasystoles, the number of instances is at present limited. A careful perusal of the literature has resulted in the following list of cases:—

Name.	Ventricle, rate and rhythm.	Remarks.
1. K. F. Wenckebach.	54, regular.	Block itself due to digitalis.
2. J. D. Windle.	66, ,,	No digitalis.
3. J. Mackenzie.	70, ,,	Block itself due to digitalis.
4. Meyer.	54, slightly irregular.	,, ,, ,, ,,
5. ,,	54, regular.	,, ,, ,, ,,
6. Neuhof.	54, slightly irregular.	No digitalis.
7. T. Lewis.	90, regular.	Complete block due to digitalis; auricles fibrillating.
8. E. H. Hunt.	64, ,,	No digitalis.
9. Hewlett and Barringer.	108, regular, but only brief phases.	Strophanthus poisoning. Auricular rate only 96. Shortly before death.
10. C. E. Lea.	60, regular.	Organic block. No digitalis.
11. ,,	75, regular.	Block due to digitalis; auricles fibrillating. (Fig. 5.)

THE LANCET (present cases).

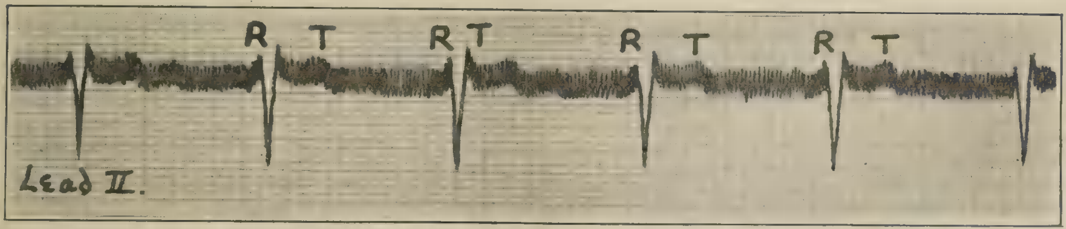
It will be clear from this list that the large majority of instances of high idioventricular rate are due to digitalis. That this drug can also influence the ventricular rhythm in other ways than simple acceleration has been shown in a few cases recently published,[2,8,10] in which, though the rate was not affected, the rhythm and the form of the ventricular complexes were modified. Such facts bring into relief the unusual feature in the case here reported, in which no drug influence was present.

FIG. 5.



Complete heart-block with auricular fibrillation (from the Electrocardiographic Department, Ancoats Hospital). Ventricular rhythm is regular at rate 75 per minute. Patient, a man aged 78, on full doses of digitalis.

(*b*) *The auricular rate.*—The slowing of the auricle over the brief period noted was due to sinal bradycardia. There was no sino-auricular block, as the rhythm was quite regular, and atropine caused acceleration without any modification of the rhythm. I have only been able to find two other clinical cases where, in complete block, the ventricular rate exceeded the auricular. One was Meyer's case, where digitalis had induced a 3–1 sino-auricular block, causing an auricular frequency of 18 per minute. Case 9 in above list is the second instance. The marked auricular acceleration to 200 following atropine represents, I think, the maximum effect from this drug so far recorded. These two observations suggest a high degree of vagal tone over the auricles, and possibly such tone may have been exerted upon the ventricle in this case, for it is unusual for vagal pressure in the neck to affect the ventricular rate, when there is complete block, whereas left vagal pressure here showed the ventricular rate 38 per cent.

(*c*) *Synchronous A.-V. contractions.*—Reference has been made to the tracing (Fig. 3) in which an apparent 3–1 A.-V. rhythm was due, in reality, to each ventricular contraction falling synchronously with each third auricular beat. That this was not merely an accidental relationship is shown by the fact that on more than one occasion a ventricular contraction fell exactly with a second auricular beat (as at ×, Fig. 3). Whilst this event was often noted on this day, other parts of the tracings showed an occasional typical ventricular extrasystole, and in such instances there was no relationship between such premature beat and the auricular contractions. The time interval separating the premature beat from the preceding normal contraction was exactly a second; the interval where the ventricular beat fell with the second auricular contraction was 1·2 seconds. It is, of course, possible to explain the synchronous A. and V. contractions on the basis that the ventricular contraction was also here a premature beat which happened to fall with the auricular beat, but the increased time interval which separates it from its preceding normal beat as compared to the instances of undoubted extrasystole makes one hesitate to accept this fully. As it happens, too, there is an apparent precedent for this observation in a case reported by Herrick.[14] In his case there was an exact 5–2 A.-V. ratio; ventricles 33·6, auricles 84. Here each second ventricular contraction coincided with the auricular beat. One is content here simply to place this observation on record without offering any explanation of its possible cause.

Conclusions.—1. A clinical case of complete heart-block, of organic nature, is recorded which showed: (*a*) persistent high idioventricular rate of 60; (*b*) a period of sinal slowing to 51, during which time the auricular rate exceeded the ventricular; (*c*) an unusual auricular tachycardia, following atropine, to 200 per minute; and (*d*) synchronous auricular and ventricular contractions during an apparent 3–1 block, such synchronism being maintained even when some degree of ventricular arrhythmia was present. 2. Digitalis seemed to have no effect upon the rhythm or rate. 3. Consideration of the hitherto reported cases of high idioventricular rate, relatively few in number, shows that the great preponderance of such instances are due to digitalis, whether or not the auricles are acting normally. Even where the rate is unaffected digitalis may influence the type of ventricular complex.

A CASE OF WAR WOUND INFECTION BY AN ANTHRACOID BACILLUS,

THE WOUND BEING CAUSED BY A SHATTERED TRIGGER-GUARD.

BY A. W. SHEEN, M.S. LOND., F.R.C.S. ENG.,
LIEUTENANT-COLONEL, ROYAL ARMY MEDICAL CORPS (T.F.).
With Pathological Report by Temporary Lieutenant B. G. KLEIN, R.A.M.C.

THAT the routine examination of the germ infections of gunshot wounds may sometimes yield unusual results is shown by the following case. It was thought at first that the infection was by the anthrax bacillus, but more detailed investigation showed that the organism was of the variety known as anthracoid. The mode of infliction of the wound—by a shattered trigger-guard—is also of interest.

Private A. G——, aged 24 years, was wounded by a bullet on Dec. 15th, 1914, at 8.15 A.M., in the palm of the left hand and in the right index finger. He estimates the range at about 30 yards. When wounded he was advancing across a turnip field with a clay soil and was holding his rifle, prepared to fire. Both hands were wounded at the same time. He dropped the rifle at once and does not know to what extent, if any, it was damaged. Because of heavy fire he lay out after being shot for about ten hours and then crawled back to his trench, getting the wounds all smeared with soil. The first field dressing was applied, and he proceeded to the base, his wounds being cleaned and dressed (apparently painted with tincture of iodine) several times. He was admitted to hospital on the afternoon of Dec. 17th.

On admission his right index finger presented an extraordinary appearance, well shown in the photograph (Fig. 1) taken four days later. The finger was stiff, nearly extended, and very much swollen round its centre, with over the dorsal surface of its middle part a protuberant ulcer, the base of which was partly covered by an adherent black slough, and partly glazed pink, with adherent fragments of grey slough and of lymph. The swelling was hard and not tender. When the photograph was taken most of the black slough had come off. Proximal to the ulcer was a "gutter" wound in the line of the finger as if the bullet had passed there. On the back of the hand were a number of linear black scabs of varying lengths suggesting small superficial wounds. The whole hand was slightly swollen. Above the wrist the limb was normal. There were the entrance and exit wounds of a bullet through the palm of the left hand. The temperature was normal and continued so, and there was no constitutional disturbance throughout.

The X ray appearances are shown by the photograph (Fig. 2). The proximal phalanx is fractured. It seems as if the bullet, after passing through the palm of the left hand, hit the trigger-guard and pulverised it, the tiny fragments being carried into the right index finger behind the trigger-guard.

FIG. 1.

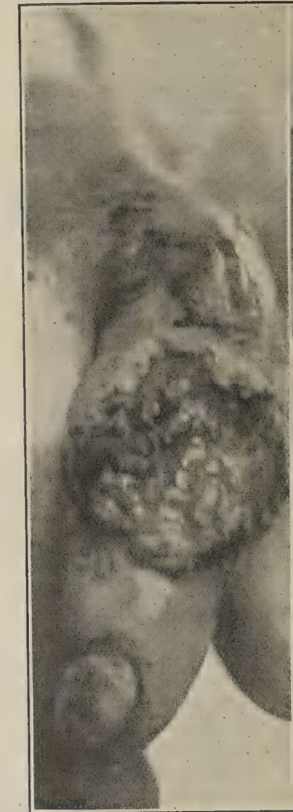

FIG. 2.

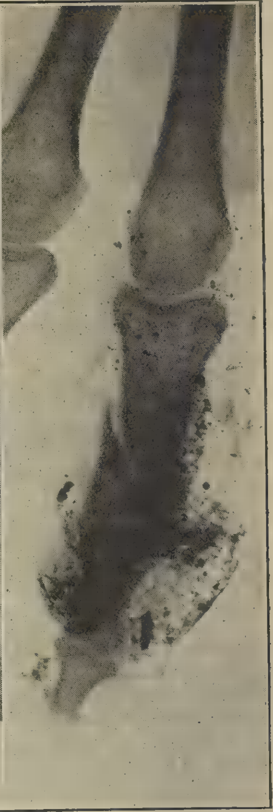

Under boric fomentations and hot iodine baths the swelling subsided, healing took place rapidly, and the use of the finger was to a large extent restored. A sinus on the dorsal surface, where the ulcer was, persisted, and this was scraped by Lieutenant J. S. Rowlands on March 29th, and subsequently healed, the man leaving the hospital on April 20th. The left hand gave no trouble; cultivations from it showed the usual pyogenic organisms.

Pathological Report by Lieutenant KLEIN.

Dec. 19th, 1914: Scrapings examined from the necrotic area on the back of the forefinger of the right hand. (*a*) Smears direct from the material showed, in addition to a very large number of streptococci, some thick straight bacilli, staining by Gram. These occurred separately, in pairs, and in short chains. The ends were nearly square. The length varied, being greatest in the single forms, in which it measured more than the diameter of a blood disc. The thickness of the rods varied from one-third to one-quarter of the length. No sporing forms were seen. (*b*) Cultures. Anaerobic culture in milk yielded no result (heated to 80° C. for 15 minutes after inoculation). Aerobic culture at 37° C. in 24 hours showed, in addition to streptococci and B. coli, a few opaque white colonies, partially confluent, of irregular outline and granular appearance. The edge of such a colony, and of similar colonies in subculture, showed an arrangement similar to that of the anthrax colony.

Microscopical examination showed cylindrical rods, with sharply defined ends (not, perhaps, quite so square cut as the typical anthrax bacillus), Gram-positive, and spore-bearing, the spore being central or nearly central. The bacilli were arranged in long chains. In the agar culture most of the bacilli appeared to be non-motile, but a certain number showed movement. In bouillon at 37° C. an abundant growth occurred in 24 hours. A certain amount of filmy growth was present in the supernatant fluid, but the bulk of the resulting mass fell and formed thick white flocculi at the bottom. The bacilli occurred here also in chains. In the 24 hours' culture they were distinctly motile.

Gelatine surface culture at 20° C. showed pin-point colonies in 24 hours; liquefaction in three days. Gelatine stab culture at 20° C. (using 7½ per cent. gelatine) produced a typical spiking growth similar to that of the anthrax bacillus. The surface growth on blood serum was similar to the stroke culture on agar, the edge of the growth showing the same furry appearance. No liquefaction of the medium occurred.

Dr. F. W. Andrewes, of St. Bartholomew's Hospital, kindly examined a culture of this bacillus and inoculated a mouse with it. He reported that the bacillus was motile and therefore could not be the anthrax bacillus. The mouse inoculated with 1 c.c. of a 24 hours' broth culture under the skin of the back died in 24 hours. In the dead mouse the chief difference from anthrax was that the intestines were distended with turbid fluid, while the spleen was enlarged and dark, and a film from it showed fairly numerous bacilli like anthrax, but the majority of them were quite actively motile.

The bacillus above described, therefore, although resembling the anthrax bacillus in some particulars, is not identical with it. It belongs, in all probability, to a class of organisms which have been described and termed "anthracoid"; one at least has been found which has some degree of virulence. Bainbridge has described such an organism as B. anthracoides. Dr. Andrewes has cultivated such a bacillus from horsehair.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

STOMACH *V.* HEART IN RELATION TO PRÆCORDIAL PAIN AND SUDDEN DEATH.

BY C. J. SORTAIN HANCOCK, M.D. DURH., M.R.C.S., &c.

IN connexion with the letters which have recently appeared in your columns on the above subject, the following case may be of interest.

A man, aged 60 years and looking much younger, recently sought advice for attacks of angina. The nature of the attacks is as follows. After any severe exertion, such as walking up hill, or if any ordinary walk is taken directly after food, severe pain commences in the upper part of the thorax, spreading to the neck, shoulders, and down both arms; it rapidly increases until it is impossible for him to move. The moment, however, he stops still the pain quickly begins to pass away, the duration of it being only from 30 to 60 seconds. If he starts walking again directly the pain returns, but after a short time he is able to walk slowly without pain. If the stomach is empty he can do ordinary walking as well as any man of his age. These attacks have occurred for the last two years with the same characteristics.

The previous history of his case which has a direct bearing on it dates from 1880, when, living in India, he suffered frequently from intermittent fever and also had severe attacks of acute gastritis, which continued in spite of treatment until he took change of air on the Brahmapootra. Then all the stomach symptoms disappeared in 24 hours, and he was able to resume his ordinary diet. He led an open-air life, and was in the saddle practically all day long. He spent in all 25 years on the plains of India, with only two holidays of ten months each. In 1885 he had broncho-pneumonia which laid him up for nearly three months and left him with a damaged lung and severe daily attacks of asthma. After these had lasted for 2½ years the paroxysms, in the middle of a hot rainy season began gradually to subside, and in a few weeks ceased, and he has never had any since.

The anginal pains came on two years ago, as above described, and do not appear to have varied in character. He has always been a total abstainer from spirits and has never had syphilis. The gastric symptoms also recurred, and he is now liable to periodic attacks of acute dyspepsia, any food at first causing severe pain, but this phase passes off and the hunger syndrome ensues. In addition to this he has occasional slight glycosuria. The heart on physical and X ray examination presents no abnormal signs whatever, and the aorta appears normal. The arteries show no signs of sclerosis. Blood pressure: 124 systolic; 80 diastolic.

For this case it would appear that if the hyper-sensitive segmentary centres are in any way responsible for the attacks they must occupy a secondary, not a primary place—for no surface pains or points of tenderness on the chest wall are complained of during the attacks, and no relief is afforded by eructation of gas, although the attacks seem to be in the large majority of instances secondary to gastric disturbance. At the same time it must be remembered that the lung trouble he complained of in 1885 resulted in frequent attacks of asthma which persisted over a space of 2½ years and then suddenly left and have never returned. I would therefore suggest that if the angina is in any way connected with the "spinal segments" the connexion is of a reflex rather than of a direct character.

Leytonstone, N.E.

POISONING BY "SPIRITS OF SALTS."

BY H. FAIRFAX, L.M.S.S.A. LOND.

I REPORT this case, although it occurred in my practice nearly five years ago, because circumstances have made it topical.

On the morning of August 31st, 1910, I was called to see a patient, and was told by his wife that he had taken about two ounces of spirits of salts. I found that he had swallowed nearly two ounces of "partially killed spirits of salts" with suicidal intent. The whole of the inside of the mouth and throat as far as one could see was corroded and discoloured by the action of the acid. I administered bicarbonate of soda in milk and water and ordered the patient to take as much milk and water, with a pinch of the powder in it, as often as he could be induced to take it. Sickness and diarrhœa continued the whole day. On the next day I gave a mixture of tr. chlorof. et morph. and liq. bismuthi to quiet the stomach and stop the diarrhœa, raw eggs and milk being the food ordered. The patient's condition improved considerably.

On Sept. 7th I removed with the forceps a traumatic diphtheritic membrane from the uvula and palate, which was considerably interfering with the breathing. Had I not known the history of the case and only seen the patient for the first time on this occasion I should have had no hesitation in stating that it was a very bad case of diphtheria. I took some of the membrane to Dr. John Biernacki, the medical superintendent of the Plaistow Fever Hospital, who said it looked like an ordinary case of diphtheria until I gave him the history of the case. He kindly had the specimen examined for me with negative results. An ordinary gargle of biborate of soda removed the false membrane and the mouth was quite clear and in its normal condition by the tenth day. The patient was decidedly better, but was complaining of intense pain all over the region of the stomach, with a sensation of choking and suffocation. The temperature and pulse were normal. Four days later (Sept. 11th) he felt sick and said he had a lump coming up in his throat, and he thrust his fingers as far down as he could to bring it up. What he brought up frightened him. This vomit appeared to me from its shape to be a complete cast of the whole of the œsophagus and stomach. After floating it out in water and examining it, I told his wife to save it and place it in a small glass jar. She unfortunately let the basin fall on the floor and smashed it, but gathered it up as well as she could, and I have placed it in spirit. On the next day vomiting again set in, the vomit being mixed with bright arterial blood. Iced milk, sugar dissolved in cold water, and minim doses of dilute liq. ferri perchlor. were given three or four times daily. The patient had very little sickness subsequently, and seemed to be in a fair way toward recovery. His diet was restricted to milk and oatmeal flour, with other like soft and pulpy foods.

On Oct. 5th the patient walked to the surgery for the first time since taking the acid, and stated that he was feeling quite himself again, and that he hoped shortly to resume his ordinary work. He asked if he might have a little more substantial food. I gave him permission and told him to be very restricted in his diet. On the 7th he called again, stating that he had had a relapse and was vomiting everything he took in the shape of food. He also informed me that he had taken a mutton chop, greens, and potatoes. I examined the urine; its specific gravity was 1035 and it was acid in reaction, no sugar or albumin being present. The heart sounds were normal and the pulse-rate was 84 and regular in force and rhythm. There was hyperresonance over the upper part of the left lung.

The patient expressed a desire to go to a hospital and see if anything further could be done for him. He was admitted to Charing Cross Hospital, an operation was performed on Nov. 2nd, and he unfortunately died from shock.

Plaistow, E.

A NOTE ON PLAGUE BACILLI IN AN UNUSUAL SITUATION IN THE BODY.

BY J. H. SHELDON, M.B. LOND., &C.,
DISTRICT MEDICAL OFFICER, BURMA RAILWAYS, INSEIN, BURMA.

AT 8.30 A.M. on Nov. 29th, 1913, I received information that an adult Burman male was in a dying condition, after an illness of 36 hours only, and that during the past hour convulsions and head retraction had been present. The sub-assistant surgeon was sent to see the man, and instructed to obtain slides of the cerebro-spinal fluid in addition to those of the blood, as it seemed possible that the case might be one of epidemic cerebro-spinal meningitis. He arrived at 9 A.M. to find the patient dead. A superficial examination of the body failed to discover any bubo or other gross lesion.

Specimens of peripheral blood were stained with gentian-violet and of the cerebro-spinal fluid with carbol-fuchsin, and examination of the slides revealed the presence of typical plague bacilli in small numbers; the slides of the cerebro-spinal fluid simply swarmed with them.

I have to thank the chief medical officer of the Burma Railways for his permission to publish the case.

Insein, Burma.

ROYAL SOCIETY OF MEDICINE.

SECTION OF OPHTHALMOLOGY.

Exhibition of Cases.—Retinitis of Pregnancy.

A MEETING of this section was held on June 9th, Mr. PRIESTLEY SMITH, the President, being in the chair.

The following cases were shown:—

Mr. A. C. HUDSON: A case of Sympathetic Ophthalmitis treated by salvarsan and neosalvarsan. It was regarded as an undoubted case of the condition, and seemed a genuine cure.

Mr. J. S. HOSFORD: Two cases of the Albuminuric Retinitis of Pregnancy.

Mr. C. N. ATLEE: Coloboma of the Iris in mother and child.

Mr. CHARLES WRAY: Bony Growth in the Frontal Sinus. In cases of retrobulbar neuritis suspected to be of sphenoidal origin, he advocated making the patient spend some time with the face downwards, with a view to facilitating drainage from the sphenoidal and posterior ethmoidal cells.—Mr. W. T. HOLMES SPICER discussed the case.

Mr. J. HERBERT FISHER read a paper on Retinitis of Pregnancy. He had not included in the title the term "albuminuric," as he wished to lead his hearers away from the idea that the acute retinal changes were the results of the kidney disorder. Obstetricians now no longer explained the albuminuria of pregnancy as the result of obscure reflex effects of the gravid uterus upon the kidneys, or by mechanical pressure on the ureters. They attributed it, with eclampsia and pathological vomiting of pregnancy, to toxæmic products in the circulation. Eclampsia could not be predicated by any examination of the urine; the effects were especially seen in the quality of the blood and in the blood-vessel walls. In fatal cases of eclampsia, hæmorrhages of brain and necrotic changes in the liver were often found, and albuminuria was an effect of the disease on the kidney, not the cause. In the retinitis of pregnancy the condition of retina was different from that in albuminuric retinitis, as also was its sequel. Syncytiotoxins—products of the disintegration of the syncytium cells—had been found in these cases, and these cells immediately connected the fœtal with the maternal structures. Mr. Fisher proceeded to give particulars of a series of typical cases of the condition which had been under his care. In one fatal case Mr. A. C. Hudson made a pathological examination on the day after death, and found the coats of the eye *in situ*. There was some œdema of the nerve head, and in the nasal quadrant of the retina were two large hæmorrhages. The microscope showed the sclera and nerve sheaths to be normal, the chief pathological changes being in the large choroidal arteries, many of which showed gross endarteritis, causing in some instances obliteration of the vessel lumen. Some of the choroidal arteries were normal. Similar pathological changes were found in sections of posterior ciliary arteries surrounding the optic nerve behind the eyeball. Bruch's membrane was everywhere intact and the retinal pigment normal. The retina and optic nerve head showed evidence of œdema, in the former almost limited to the internuclear layer. Rods and cones were almost entirely absent, but this may be attributable to post-mortem changes. In the large retinal veins there was pronounced thickening of the adventitial coat. He had found it difficult to group his cases. The rule had been for good recovery of vision to ensue, with the disappearance of all acute manifestations in the retina, thus differing absolutely from cases of ordinary renal retinitis. In cases in which defects of vision were permanent, this seemed to have been because changes had been produced in the walls of the arteries or an atrophic condition of the nerve. A recurrence of the retinitis was not necessarily seen when subsequent pregnancies occurred, even though the albumin did not quite disappear in all. One of his patients died after an interval of six years from cardiac failure; another after eight and a half years from cerebral hæmorrhage into the left corpus striatum. In this case the kidneys were found to be of the typical red granular type. It seemed clear from his cases that albuminuria of pregnancy was not sufficient alone to set up the typical retinitis of pregnancy.—In the ensuing discussion Mr. HOSFORD, speaking of retinitis, reported having carefully observed 16 cases during the last 15 years; only three of those patients were now alive. All but two ultimately developed a star-shaped spot on the macula, a sign which he regarded as of fatal omen. Many patients seemed quite to recover from the initial attack; a relapse occurred later. In a series of 132 cases in Dr. S. Fenwick's wards 81 were in females, 51 in males; the onset among single men and single women seemed to be about equal. Much of the renal trouble seen fairly late in life might have started, in females, in pregnancy. Only 3 of the 132 cases had myopic eyes. Since the Wassermann reaction was introduced he had had all the cases he saw tested, but none was syphilitic.—Mr. W. C. ROCKLIFFE related a case in which retinitis occurred in the first pregnancy, but the defect of sight seemed to be quite recovered from after premature labour was induced. A subsequent pregnancy brought on a repetition, but though labour was again ended prematurely, sight became progressively worse and ended in blindness. The patient died four years later from heart failure.—Mr. J. B. LAWFORD alluded to the far-reaching effect of the toxæmia. In some of his cases, although there was no recrudescence of retinal change during subsequent pregnancies, toxic effects showed themselves at a later date and eventuated fatally. It was a common belief that one of the safeguards in this condition was the avoidance of further pregnancies in the patient. In one case which he had under care over 20 years ago the lady developed retinitis in her first pregnancy, and had great defect of sight. This disappeared after delivery, and, acting on the advice of her medical attendant and himself, she had no further pregnancies. Her sight remained good for a number of years, but ultimately she developed advanced changes in the retinal vessels, and succumbed to chronic nephritis. Another patient, older, developed the condition in her third pregnancy, and recovered. The advice to bear no more children was disregarded, and in her next pregnancy there was a great aggravation of her toxæmic condition, and she died from nephritis. He asked whether obstetricians were aware of the reason for the persistence of the toxic effects of the first attack, even though some subsequent pregnancies did not seem to be accompanied by the symptoms. There seemed to be need for a revision of the view as to the comparative innocuousness of the retinitis of pregnancy.—Mr. LESLIE PATON regarded the paper as important in that it gave a broad view of a disease not apparently due to a microbial poison, but to a cytotoxin; and he tentatively suggested that such conditions as the irido-cyclitis seen in women at the period of the climacteric would possibly be brought into the same category. The seriousness of the disease seemed to be directly proportional to the extent to which the vessels were injured at the time of the attack. One case, though presenting "silver-wire" arteries, remained still well eight years after the attack. He was much interested in the statement of Mr. Fisher that subsequent pregnancies need not necessarily cause a recurrence of the retinitis, for it touched a matter on which advice was frequently asked.—Mr. FISHER replied, suggesting combined investigation by obstetricians and ophthalmologists concerning the diseases attributable to the toxæmia present in pregnancy.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF SURGERY.

Exhibition of Cases.—Bridge Method of Skin Grafting.

A MEETING of this section was held on May 14th, Dr. F. CONWAY DWYER, the President, being in the chair.

Mr. D. KENNEDY showed a girl who, some nine or ten months ago, injured her elbow by a fall. Since then there was complete ankylosis. When first seen about a month ago, X ray examination showed that the humerus was not normal, but somewhat battered. It was decided to perform an arthroplasty or whatever treatment was suggested by the condition found. A projection was found on the inner side of the articular end of the humerus. The projection was removed off the ulnar aspect of the humerus and the end of the humerus was put level. A flap was then taken partly from the lateral aspect of the arm, and almost entirely consisting of fat, and turned over the humerus, leaving the ulna and radius as they were.—The PRESIDENT and Mr. H. DE L. CRAWFORD discussed the case, and Mr. KENNEDY replied.

Mr. H. DE L. CRAWFORD showed photographs of four cases of Congenital Syphilis of the Hands and Feet. The skiagrams were brought forward, as congenital syphilis of the hands and feet was considered a rather rare condition. The first was in a boy, aged 11 years, with a very large swelling on the outside of the left foot and a good deal of thickening in the soft parts. The patient had well-marked Hutchinson's teeth. When the photographs were taken the condition had spread to the proximal phalanx of the big toe. The X rays pointed to the condition being gummata underneath the bone. He suggested that what appeared to be small sinuses were really pieces of dead bone. Under continued treatment with mercury and iodide of potassium the gummata healed up. The second case was that of a boy who had also well-marked Hutchinson's teeth. The patient was the only living child in the family, and there was a history of six miscarriages. The thumb was very swollen, and the phalanges showed small areas of rarefaction. There was no pain, so the condition was not looked upon as tuberculous. There was no sign of ordinary or syphilitic rickets. The third case was that of a baby, aged 1½ years. The child was an adopted one, and no definite family history was forthcoming. There was much metacarpal thickening. The child had a typical syphilitic forehead, and the absence of increased heat, tenderness, or pain made it positive that the case was not one of tuberculosis. The fourth case was that of a child with swollen ring finger on the left hand. Amputation of the finger was advised. On cutting down to the periosteum the extensor was found to be involved, and a soft, gritty substance, apparently new bone, was seen. The wound healed. A week later there was slight enlargement of the other hand. The case was considered syphilitic. Family history was bad, showing three previous miscarriages. This condition, he said, appeared to be more common than was expected, and he had decided in future not to label any of these cases as tuberculous until they had been well examined.

Mr. CRAWFORD also showed skiagrams of old Traumatic Dislocation of the Hip in a child aged 9.—The PRESIDENT said that the point raised in connexion with these cases was of much importance, as they were all likely to diagnose them as tuberculous instead of syphilitic.

Mr. CRAWFORD afterwards read a paper on the Bridge Method of Skin Grafting. After describing the technique in detail, he emphasised the following points: (1) That asepsis must be perfect; (2) that the size of the graft must be as small as possible, and that it was better to operate twice than use a very big graft; and (3) that the graft and limb must be very carefully immobilised during the first week. (The paper was illustrated by lantern slides.)—The PRESIDENT expressed the indebtedness of the section to Mr. Crawford for bringing forward this effective method of treatment. This method of grafting, which left the graft on the exposed raw surface, evidently yielded good results. He considered the technique described one that ought to be followed.—Mr. KENNEDY considered the Bridge method a most ingenious one, and if the difficulty of covering a large area could be overcome he would be glad to hear how it could be done.—Mr. M'CONNELL said he had treated one case by this method—viz., a very extensive formation of scar tissue on the thumb. The result pleased him very much, and the patient had very good abduction in the thumb afterwards. Skin grafting seemed to be absolutely different in the hand from elsewhere, as in other parts a good blood-supply was to be had, whereas the supply in the hands was bad. In all cases of grafting about the hands and feet he looked upon the Bridge method as the only one. He suggested that all methods might be used in their proper places.—Mr. CRAWFORD, replying to the remarks, said that the method which should be used entirely depended upon the site on which the graft was to grow.

SECTION OF MEDICINE.

Exhibition of a Case of Leprosy.—The Use of Vaccines in the Treatment of Respiratory Diseases.

A MEETING of this section was held on May 21st, Sir JOHN W. MOORE being in the chair.

Dr. C. M. O'BRIEN showed a patient suffering from Leprosy of the tuberculated form. The patient was a retired soldier who had offered himself for service, but was refused on account of a rash on his skin. He had served in the Leinster Regiment in Malta, Bermuda, Halifax, Jamaica, and South Africa. He had had colic in Malta and gonorrhœa in the year 1898, but had never had syphilis. He left the army in 1906 apparently perfectly well and had worked as a farm labourer. In 1913 he was in hospital for five months with boils on the face and neck. The disease was first diagnosed in August, 1914. The face as a whole was unusually broad, the chin being prominent; the skin on the forehead lumpy and shiny; the nose flattened; the lips thick; hair, other than on scalp, falling out; the hands swollen and cushion-like on back, ash-grey in colour; thenar and hypothenar muscles flat and flabby; inguinal glands shotty; reflexes normal; no anæsthesia. Mucous membranes free. No reaction with alt-tuberculin injected subcutaneously nor by von Pirquet's method. Positive Wassermann reaction. Sections from a nodule, prepared by Mr. T. T. O'Farrell, were exhibited showing the bacilli in numbers; a few in cells, the majority extra-cellular. Dr. O'Brien gave an interesting résumé of the history of leprosy, and dealt especially with recent investigations into its bacteriology and transmissibility.—Sir JOHN MOORE, Dr. H. C. DRURY (who reminded the meeting that such names as Lazarus Hill and Leopardstown, marking leprosy stations, showed the former presence of the disease in Ireland), Professor METTAM, Dr. W. M. CROFTON, and Dr. F. C. PURSER also spoke.

Dr. ROBERT J. ROWLETTE read a paper on the Use of Vaccines in the Treatment of Respiratory Diseases, which will appear in THE LANCET.

LONDON (ROYAL FREE HOSPITAL) SCHOOL OF MEDICINE FOR WOMEN (UNIVERSITY OF LONDON).—The Queen has announced her intention of attending the special matinée at the Palace Theatre on June 29th, at 2.30 P.M., when the proceeds will go to the London School of Medicine for Women.—The presentation of prizes will take place on Thursday next, June 24th, at 4 P.M., by Her Royal Highness Princess Alexander of Teck, when academic dress will be worn. Intending guests should communicate with the secretary, 8, Hunter-street, Brunswick-square, London, W.C. The company is asked to assemble at 3.45 P.M., after which time admittance will be only to the garden by the entrance in Handel-street.

GLASGOW CORPORATION AND THE TREATMENT OF PHTHISIS.—The Glasgow Corporation have under discussion a proposal to convert the tramway depôt at Ibrox into a temporary hospital for the treatment of tuberculosis. The scheme, which will involve an expenditure of £8000, provides for the accommodation of 240 patients, many of whom have had to be removed from other institutions taken over by the military authorities. The proposal has met with strong disapproval from the inhabitants of the district and from the Govan school authorities on the grounds that the health of the children will be jeopardised.

Reviews and Notices of Books.

The Dispensary Treatment of Pulmonary Tuberculosis.

By HILDA CLARK, M.B., B.S. Lond., late Honorary Medical Officer, Street Tuberculin Dispensary, and Tuberculosis Medical Officer to the County Borough of Portsmouth. London: Baillière, Tindall, and Cox. 1915. Pp. 279. Price 15*s*.

IN this volume Dr. Hilda Clark describes in detail a complete series of cases for whose examination and treatment she was responsible for the three years from June, 1910, to June, 1913. She explains that the investigation was carried out with three main objects in view. 1. To estimate the value of tuberculin treatment by two consecutive series of cases. 2. To estimate the position of tuberculin treatment in a scheme designed to deal with the special problem of tuberculosis in the working classes. 3. To estimate the incidence, course, and response to treatment of tuberculosis in the population of Street, a manufacturing village in Somerset, where peculiar opportunity offered for such an investigation.

It is in regard to the first two of the above propositions that the chief general interest arises. Dr. Clark has evidently expended a vast amount of time and care in the investigation of the cases and the collection of results, but owing to three main reasons, in our opinion, she fails to establish the fact that tuberculin is such a valuable therapeutic preparation as has been claimed by some observers. In the first place the classification she has adopted of the various types of cases is so involved that it is difficult to follow. Secondly, she has not contrasted her results with those obtained by other means of treatment. Thirdly, the time during which the patients were under observation was too short to enable a reliable opinion to be formed as to the permanency or otherwise of the arrest of the disease. On the other hand, however, the careful description of a large number of cases tends to show that with due care in the administration of the remedy harmful sequelæ rarely occur.

Needless to say, the best results were obtained in those cases in which tubercle bacilli were not found, and in connexion with this fact it is interesting to note the statement that the discovery of the tubercle bacillus in the sputum is considered by Dr. Clark to be the only certain proof that the lungs are infected; with this view the large majority of physicians who have had an extended experience in connexion with the disease will be cordially in accord. We also commend the opinion that the occurrence of either a general or a needle-track reaction after the subcutaneous injection of tuberculin indicates that infection of some part of the body has occurred at some period. But if a focal reaction can be detected it is considered that active mischief must be present at the spot where it was observed. These views are perfectly in accord with modern research.

In discussing the value of tuberculin as a remedial agent, Dr. Clark is not convincing. Her words cannot be considered to carry much weight when she says: "In studying the cases ...... with a view to obtaining evidence as to the action of tuberculin the first general impression must certainly be that the remedy has been of use," and the subsequent remarks by no means add force to this statement.

We do not wish to intimate that we consider that the administration of tuberculin is useless, but merely to express our opinion that the series of cases recorded in this volume have not proved that tuberculin is superior to the other methods of treatment of pulmonary tuberculosis which are now being employed.

A Text-book of Practical Therapeutics.

By HOBART AMORY HARE, M.D., B.Sc., Professor of Therapeutics, Materia Medica, and Diagnosis in the Jefferson Medical College of Philadelphia; Physician to the Jefferson Medical College Hospital. Fifteenth edition. London: Henry Kimpton. 1914. Pp. 998. Price 21*s.*

THE fact that 15 large editions and many reprintings have been called for since this book first appeared in 1890 leaves little room for question that the author's effort to write a trustworthy and useful text-book on therapeutics has proved successful. Dr. Hare points out that the present time is an era of therapeutic rationalism, when remedies are given, not because they are recommended or their value is proclaimed by some authority, but because their use appeals to the medical practitioner who has a knowledge of the physiological, pathological, and therapeutic problems to be faced, and therefore judges for himself what remedy is best suited to a given case. Dr. Hare has therefore studied how best to give an account of remedial measures for disease and their employment upon a rational basis.

As in previous editions the work is divided into four parts. The first deals with introductory matters, the second with the action of drugs, the third with remedial measures other than drugs, and the fourth with the treatment of individual diseases, whereby the employment of the remedies discussed in the earlier part of the book is directly applied, as at the bedside.

The book has been brought thoroughly up to date, and certain articles have been added or rewritten. In the discussion of the use of tuberculin as a remedial agent preference is given to the method of employing infinitesimal doses, so that no febrile reaction is produced. A good account is given of the therapeutics of salvarsan, and the modes of its administration are clearly described.

The book continues to be found a most useful one for reference; its vast amount of valuable information is steadily sifted and increased by recurring issues.

A Laboratory Manual and Text-book of Embryology.

By CHARLES WILLIAM PRENTISS, A.M., Ph.D., Professor of Microscopic Anatomy in the Northwestern University Medical School, Chicago. With 368 illustrations (many in colours). London and Philadelphia: W. B. Saunders Company. 1915. Pp. 400. Price 17*s.* net.

IF this text-book represents the actual course on this subject given in the Northwestern University Medical School of Chicago, then it is evident the medical students of that University obtain a fuller and more practical course on this subject than falls to the fortune of our students at home. It represents an attempt to combine descriptions of vertebrate embryos which are studied in the laboratory with an account of human embryology especially adapted to the medical student. The emphasis in this sentence is clearly on the word laboratory as opposed to mere descriptive lectures or demonstrations. The author appeals for a greater attention to the study of embryology because it affords a comprehensive understanding of gross anatomy of the adult, and also because it explains the occurrence of many anomalies as well as certain pathological changes in the tissues. We quite agree with him, but in a medical course already overburdened with various subjects our wonder is how the average medical student can find time to carry out the many manipulations required for the dissection of pig embryos which are so carefully described and well illustrated in the text. The chapters on human organogenesis are partly based on Keibel and Mall's "Human Embryology."

The following is the arrangement of the subject matter: the germ cell, segmentation and formation of the germ layers, study of chick embryos, fœtal membranes and early human embryos, pig embryos and methods of dissecting them, the development of face, palate, tongue, salivary glands, entodermal canal and its derivatives, urogenital and vascular systems, histogenesis, morphogenesis of the central and peripheral nervous system.

A list of about a dozen of the newer principal text-books is given for reference. The illustrations are numerous, bold, clear, and well printed. Some are borrowed and their sources duly acknowledged. Careful descriptions are given of the various sections of embryos which are inserted in the text, and rather full descriptions of them necessarily occupy a considerable part of the text itself. Moreover, the magnification is carefully stated. Some of the illustrations are more or less semi-diagrammatic "reconstructions" of embryos in various stages of development. A very readable account is given of early human embryos and their membranes. About 70 pages are devoted to the study of pig embryos and their organs.

This is a lucid, comprehensive, and yet not too extensive text-book, which we cordially recommend as an attractive, practical, and succinct presentation of the main facts of vertebrate embryology. The illustrations are admirably drawn and really instructive.

LIBRARY TABLE.

An Ethical Problem, or Sidelights upon Scientific Experimentation on Man and Animals. By ALBERT LEFFINGWELL, M.D. New York: C. P. Farrell. 1915. Pp. 369.—The purpose of this book is set forth in the preface as follows: "An ethical problem exists. It concerns not the prevention of all experimentation upon animals, but rather the abolition of its cruelty, its secrecy, its abuse." In a postscript to the preface the author goes out of his way to comment on the horror of the present great struggle between the nations, and expresses the hope that "the insolence which deems the promise of a nation to be no better than a 'scrap of paper' shall meet its due recompense." As he has dragged in the war, we may be permitted to call attention to the fact that speaking in the Reichstag on May 28th the German Chancellor, Dr. von Bethmann-Hollweg, referring to Italy's joining the Allies, had the effrontery to say: "Italian statesmen have no right to measure the trustworthiness of other nations in the same proportion as they measured their own loyalty to a treaty. Germany by her word guaranteed that the concessions would be carried through. There was no occasion for distrust." The application of this parable will be found in the following words taken from Chapter XV. of the book before us entitled "Unfair Methods of Controversy": "One phase of the vivisection controversy is of singular significance. It is the peculiar tendency to unfairness which the advocates of unrestricted experimentation seem to display in every discussion regarding the practice; ...... it would seem to be impossible for anyone writing in advocacy of unlimited and unrestricted vivisection to state fairly the views to which he is opposed." Considering the repeated and continuous career of demonstrated misstatement and falsehood that has throughout characterised the crusade against scientific research, of which notable examples were given in Dr. W. W. Keen's book reviewed in these columns recently, this is quite in Bethmann-Hollweg's vein.

The Arcana of Freemasonry. By ALBERT CHURCHWARD, M.D. Brux., M.R.C.P. Edin. London George Allen and Unwin. 1915. Price 7*s.* 6*d.* net. Pp. 326.—This book is dedicated by the author to "all my brother Masons, of whatever clime and whatever creed, who take an interest in Masonic research," and is made up of a series of lectures, some of which have already appeared in the *Freemason.* This being so, the general reader will find the book somewhat recondite, but some of the chapters will appeal to those who take an interest in ritual and symbolism. Thus, Chapter IV. deals with the Divine Name, Chapter IX. with the origin and explanation of some Masonic signs and symbols, and Chapter X. with Egyptology and Masonry. (Masonry, according to Dr. Churchward, has its root in Egypt.) Chapter XII., the Operative Masons, discusses the various symbols and figures upon which the ground-plans of temples and other buildings were founded, an interesting subject, which is treated in a manner more suited to the general reader by Lethaby in his book, "Architecture, Mysticism, and Myth." We have read Dr. Churchward's book with interest, and perhaps the best comment upon it is the phrase of that learned member of our own profession, Sir Thomas Browne, who surely would recognise Dr. Churchward as a kindred spirit: "All things began in Order, so shall they end, and so shall they begin again, according to the Ordainer of Order and Mystical Mathematicks of the City of Heaven."

Index Catalogue of the Library of the Surgeon-General's Office, U.S. Army. Authors and Subjects. Second Series, Vol. XIX. U—Uzielli. Washington: Government Printing Office. 1914. Pp. 674. Price $2.—The present volume of this storehouse of all the literature of medicine—not of books only, but of pamphlets and individual articles in the medical press of the world—opens with six pages of additional abbreviations for the titles of medical periodicals to which reference is made. Among the important headings which embrace references to a wide area of literature are: United States (70 pages), Unna (4¾ pages), Urethra (41 pages), Urinary and Urine (105½ pages), and Uterus (292 pages). As a reference work to the medical literature, ancient and modern, of the entire world this laborious compilation stands unequalled.

MISCELLANEOUS VOLUMES.

UNDER the title of *Leper Houses and Mediæval Hospitals* (London: H. K. Lewis. Pp. 47. Price 1*s.* net) has been issued a reprint of the FitzPatrick lectures delivered by Dr. CHARLES A. MERCIER before the Royal College of Physicians of London on Nov. 5th and 10th, 1914, a full abstract of which appeared in our columns on Jan. 2nd and 9th, 1915. The first lecture is devoted to a historical survey of leprosy up to the middle of the seventeenth century, by which time it had practically disappeared from Europe, and Dr. Mercier concludes by suggesting that tuberculosis as at present existing is a modified form of the ancient and mediæval leprosy: "I venture to put forward the hypothesis that the bacillus of leprosy has changed in the course of time into the tubercular bacillus." The second lecture mainly deals with the constitution and management of leper and other hospitals. Our forefathers were generous in many ways to "Christ's poor," but they were also thrifty. Thus Henry IV. confirmed to the hospital of St. Giles, near Maldon, in Essex, that the master thereof was to have towards the maintenance of the leprous burghers of the said town the forfeitures of bread, ale, and fish that was not good. Some years before Henry IV.—i.e., in 1384—the Parliament of Scone had provided that "gif ony man bring to the merkit corrupt swine or salmond to be sauld they sall be taken by the bailies and inconteinent without any question at all sall be sent to the lipperfolke, and gif ther be no lipperfolke they sall be destroyed uterlie." Dr. Mercier's lectures naturally give only an outline of the important subject with which he deals. Mediæval hospitals were so bound up with mediæval life that their history, foundation, life, decline, and fall form a very large matter for treatment. Any reader of Dr. Mercier's lectures who may desire to go further into the matter will find in Miss Mary Clay's "The Mediæval Hospitals of England" an excellent book dealing with a general view of the subject, and a copious bibliography containing references to many books and papers dealing with details.

Two new volumes have been added to the "Pocket-Guide Series," published at 1*s.* each by The Scientific Press. The first is *The Muscular System,* by HAROLD BURROWS, M.B., B.S. Lond., F.R.C.S. Eng., in which the most important features of the anatomy of the skeletal muscles with their functions and nerve supplies are summarised. The second is *Notes on the Nervous System,* by EDWIN L. ASH, M.D. Lond., which contains a similar summary of the elementary anatomy and physiology of the human nervous system. These are specimens of a class of books which appeal to medical students and nurses. With regard to the students, we repeat the warning to which we have had occasion so frequently to give utterance—that such condensed guides as these can be serviceable only if properly used for reviewing knowledge acquired practically and by study of fuller works, if they are used as substitutes in either direction they are likely to be pernicious rather than useful.

The publication of the new Pharmacopœia of 1914 has been naturally followed by new editions of Pocket Prescribers and Summaries of Materia Medica. *A Conspectus of the Principal Changes of the British Pharmacopœia, 1914,* by J. H. WILLIAMS, F.C.S. (London: Corbyn, Stacey, and Co., Limited. 1915. Price 1*s.*) contains an alphabetical list of the preparations in the new Pharmacopœia, with their doses in Imperial measure, as well as in the decimal measures adopted by the Pharmacopœia and new preparations or those which have been altered from the old Pharmacopœia are indicated by a marginal letter. Preparations of the preceding Pharmacopœia which have been omitted in the present one are given in italics in their alphabetical order. There is a useful critical introduction.——*Husband's Students' Pocket Prescriber and Guide to Prescription Writing,* in its fifth edition, by Dr. DAVID MITCHELL MACDONALD (Edinburgh: E. and S. Livingstone. 1915. Pp. 122. Price 1*s.* 6*d.* net), also has been revised in accordance with the new Pharmacopœia, and so has the *Posological Tables, Appendix on Poisons, Index of Diseases and Medicines arranged according to their Actions,* fourth edition, by Dr. WILLIAM CRAIG (Same publishers and date. Pp. 132. Price 1*s.* net). Both these booklets are too well known to need any detailed description.——Yet another is the *Supplement to the British Pharmaceutical Codex, 1911,* published under the Direction of the Council of the Pharmaceutical Society of Great Britain (London: Pharmaceutical Press. 1915. Pp. 75. Price 1*s.* net), which contains particulars of important additions and alterations which have become necessary since that work was published, including new monographs, galenical formulæ, a series of formulæ for test solutions and microscopical stains, a list of the chemical equivalents of substances known under proprietary trade-names, and alterations in the text of the Codex that have been rendered necessary by the 1914 revision of the *British Pharmacopœia.* There is also a table of corrigenda for the Codex of 1911.

THE LANCET.

LONDON: SATURDAY, JUNE 19, 1915.

The Weapons of Chemistry.

METHODS of warfare have advanced enormously in technique though not in design, for the return by the Germans to the stink-pot of savagery, although elaborate scientific machinery is employed, remains a manifestation of primeval barbarity. Since the days of bows and arrows and battering-rams we seem to have made vast strides, but, as recent history clearly shows, the radical change has been chiefly a transition from physical to chemical resources. Improvements of mechanical transport and means of intercommunication, coupled with the growth of populations, have led to the formation of far larger armies, and the weapons of destruction have developed as the work required of them has grown immeasurably. And to a great extent the chemical activity has been modern. The gun itself is not a very archaic weapon, and there are still preserved amongst us early specimens of it in the shape of the flint-lock musket, with its attached ramrod for driving home the powder. It is only comparatively recently, too, that the machine gun has succeeded the cannon. Gunpowder was the only explosive known for a long time, and it was not until about 30 years ago that it was gradually replaced by the cartridge still with gunpowder in it, but later with a smokeless explosive. The introduction of the smokeless explosive or of nitro-compounds in general was the beginning of a rapid advance in firearms and artillery. It made possible the machine gun and the leviathan gun which now can project something like a ton's weight of metal to its target at a distance of 18 miles or more. Coupled with the art of the gunner it is chemistry that has made these achievements possible.

It is not difficult to find in other directions proofs that chemistry has very materially contributed to making modern systems of warfare the refinements of terror that they are. Can any more amazing agent for the purposes of war be mentioned than petrol itself? Not many years ago petrol was familiar chiefly as a light gas-smelling fluid which effectively removed grease spots from clothing, and outside its small employment in household and industrial affairs it had little application. Now it is the foundation of the gigantic motor industry. While the internal combustion engine has revolutionised the world's methods of propulsion incidentally in peace time, bringing the motor-bus and the taxi-cab into being, it has made possible the aeroplane, the dirigible, and the submarine, all of which are stern potentialities in modern warfare and are exercising a far-reaching influence on the issue of the struggle. The distillation methods of the chemist isolated this readily gasified liquid from the black viscid mass exuding from the oil well. And the submarine demands another chemical service; its crew must be kept alive while the craft is submerged, and chemistry steps in and supplies compressed oxygen to support the lives of the crews. The work of the chemist in these directions is well known to all, but recent events may well lead us to wonder whether the service of chemistry is going to be requisitioned for war purposes unaided by arms or artillery. It would be rash to assume that the future quarrels between nations are likely to be decided by the side which possesses a subtler knowledge of chemistry than the other; to talk of this war, as some are doing, as "a chemists' war" is to lose a sense of proportion, and there is little reason to suppose that subsequent events will show, for example, that poisons adroitly used will oust the accurately aimed bullet and shell. Discussion has been busy, since the enemy employed asphyxiating gases as a weapon in the field, in regard to the shapes which retaliation by this method could take. Glib references are made to the possible use of potent poisons, arsenical gases, prussic acid, or some death-dealing substance which shall improve upon the chlorine compound adopted by the enemy. It is well to remember that there is evidence that the enemy has seriously and systematically studied this question for some time, and we may be fairly certain that the gas used was decided upon after considerable trials as the most available and practicable for the ghastly ends in view. At all events, such other deadly materials as may be available are as much in the enemy's hands as in ours, and neither side would be likely to gain any permanent benefit by such machinations. We must not dismiss as impracticable the wilder dreams of the chemical poisoner, for in chemistry it would seem that no sooner is a suggestion dismissed as foolish than it at once appears in the form of accomplished fact; but we lean to the belief that the capacities of gas poisoning have been exhibited to the full. The distribution of poisons by means of bombs may add a degree of certainty to the murderous plan. The conveyance of a bank of gas along a definite line by air currents cannot always be depended upon, and it has already happened that the liberated gas has come back in boomerang fashion upon the ranks from which it was projected.

Does the time approach when owing to the high developments of chemical and physical science warfare will become well-nigh impossible? The speculation will claim greater attention in view of the new resources of the present war. According to this view, the race for supremacy will be won by that nation which is first in making fresh scientific discoveries. Possibly explosives may be rendered useless when invisible means are found to fire them from great distances, as might well prove to be the case in these days of wireless waves or radiations and projections. It would be a remarkable outcome of scientific discovery applied to modern methods of warfare if by their precision and certainty the new weapons automatically extinguished themselves. Mental subtlety may thus defeat its own ends, and as future struggles are not likely to be decided by a reversion to old-fashioned fighting methods, arbitration should at length succeed. But the man of the future in war, as he is in medicine, would seem to be the chemist.

◆

Cervical Gland Tuberculosis.

THE frequency with which enlarged cervical lymphatic glands occur renders an investigation in regard to their etiology a very interesting one. Much controversy has occurred as to the identity or diversity of the organisms which produce the condition, especially as to whether the human or bovine type of the tubercle bacillus is the more common. More recently another point has arisen—namely, whether atypical tubercle bacilli can be isolated in cases of cervical gland tuberculosis. We publish this week an investigation by Dr. A. STANLEY GRIFFITH into the subject, and he mentions that of the several observers who have made bacteriological investigations of tuberculous glands in the neck DUVAL alone claims to have isolated such organisms. These cultures bear no resemblance, judging from the information given as to cultural characters and virulence, to any tubercle bacilli hitherto described. DUVAL'S results are obviously exceptional and require corroboration before they can be accepted. The possibility of such bacilli being found in tuberculous cervical glands is, however, of some interest, inasmuch as this is the only form of tuberculosis of which lupus has been observed to be a direct sequela. It is further noteworthy that about 12 per cent. of the cases of lupus which Dr. GRIFFITH has examined have followed tuberculosis of the cervical glands, and in all but one of these cases the lupoid lesions have yielded atypical tubercle bacilli.

Dr. GRIFFITH gives the results of observations on material obtained by surgical operation from 110 persons, including children, adolescents, and adults. In the majority of the cases the actual substance consisted of lymphatic gland tissue. He divides the cases into three groups. In the first the glands were not macroscopically tuberculous and did not produce tuberculosis in guinea-pigs. Efforts to inoculate guinea-pigs from the glands in the second group of patients also proved negative, although the glands were obviously of a tuberculous character, and in many instances tubercle bacilli were found in smear preparations of the emulsions used for inoculation. In the third group, comprising 71 of the 110 cases, the original material produced tuberculosis in guinea-pigs, and cultures were obtained. It is to this group that special attention may be directed. The opinion has been expressed by many observers that the bovine type of tubercle bacillus is chiefly to be found in young life, whilst the human type is more common after 10 or 15 years of age. This is well indicated by the statistics submitted by Dr. GRIFFITH, for he shows that the proportion of bovine infections is highest in children under 5 years of age, diminishing as age advances. But in his cases the percentage of adults over 20 years of age infected with bovine tubercle bacilli is remarkably great. According to these figures, there is a marked contrast between cervical gland tuberculosis in the adult and pulmonary tuberculosis in which the bovine type is comparatively rarely found. In another table Dr. GRIFFITH analyses the cases in accordance with the locality from which they were derived. We agree that the figures are not large enough for comparative statistical purposes as between different centres of population, but none of the localities investigated seemed to enjoy freedom from risk of infection with bovine tubercle bacilli.

In the second group of cases referred to by Dr. GRIFFITH inoculation failed to produce tuberculosis in guinea-pigs; this fact would seem to bear on the prognosis of cervical gland tuberculosis. It is recognised that in glandular tuberculosis there is a tendency to spontaneous cure, and probably in the patients belonging to this group arrest of the active processes had taken place. It would be of interest to know whether the disease produced by the bovine type of tubercle bacilli is more prone to spontaneous cure than is that occasioned by the human type. Dr. GRIFFITH makes some reference to this point, but further investigation into the matter is desirable. The results of operation on enlarged glands in the neck are well known to be favourable, so are the effects of exposure to pure air and good feeding; but in estimating the comparative results of any therapeutic measures employed in connexion with tuberculous glands the tendency to spontaneous arrest must be remembered, or false ideas on methods of treatment may easily arise. Indeed, the same principle applies to the use of remedies in all forms of tuberculosis: the development of the natural resistance of the body is of primary importance, and placing the patient under favourable hygienic conditions in every way is the easiest and most practical manner in which the desired effect may be produced. The incidence of cervical gland tuberculosis is by no means confined to children or adults in large cities. In the towns and villages on the coasts of Devonshire and Cornwall, where young patients are so often sent in order to obtain the benefit of the fresh air, many children who have been born and brought up in the districts are found to suffer from the same condition, and the explanation is forthcoming when these children are seen in the shut-up rooms and unhygienic surroundings of their homes. The importance of pure air by night and by day, and suitable nourishment is accentuated by such facts.

Annotations.

"Ne quid nimis."

HOLIDAYS AND HEALTH.

IN normal times the advent of June brings with it thoughts of holidays. But these are not normal times. Owing to the great war but little, if any, consideration is being given to the annual vacation. The possibilities of the continent are gone for the time, the withdrawal of all cheap facilities on the railway will check the traveller at home, and with a sovereign only buying the same quantity of food as 15s. bought a year ago everyone has less money to spend. And as the days, the weeks, and the months of the war roll on so the demand for labour everywhere increases in every phase of our national life. Yet those who badly feel the need of some respite must be advised to take it, if they can get it, however ill-attuned they may feel, for otherwise the period may be shortened during which their work will be of any value; and especially is it the town-dweller who needs a new environment if only for a few days. The practical question, of course, is whether it would be possible to combine two sets of circumstances in some way that might be productive for the nation. There is a great deal of work to be done throughout the countryside, and a large number of urban amateurs should be available for such work from now onwards. To these the employers of labour might look for some of the help that is needed in the busy agricultural season, when even in normal times there is a difficulty in securing the required hands. Thousands of individuals at the end of July—females as well as males—will be "let loose," as it were, from their everyday toil, a very large number with a holiday of varying periods extending from two to four weeks, and many could arrange perhaps to be absent from their desks for a longer period. The suggestions which have been put forward in various quarters that these holiday-makers should occupy their time in assisting in the agriculture of the country are heartily to be commended; we should be delighted to hear that the stage of suggestion had passed to that of arrangement. We can rest assured that there will be no holidays—in the general acceptance of the term—for our enemy civil populations this summer. The Germans, for example, will not, where they can possibly help it, allow their industries to suffer for the want of labour, and it behoves all of us to see that our relaxation period is not wasted. As far as is possible the work which many of our fighting men would have been doing at home ought to be carried on by all unoccupied hands, and there is bound to be a great demand for labour in our agricultural industry. To those engaged in sedentary occupations and all brain-workers a holiday on the land helping the farmer garner in the harvest would be a real holiday both from the mental and physical health point of view. The change of occupation, change of environment, change of scene, and change of diet would prove to many an excellent tonic—as beneficial as "training" has been to those who left their offices for a suit of khaki. There should be a ready and quick response to any call for help from our holiday-makers, but the value of such assistance would be multiplied a thousand-fold if it were organised and put upon a definite basis. The grave error made by all citizens of towns is to regard agricultural labour as unskilled, whereas much of it is of a highly technical quality. The assistance of casual holiday makers need not be despised, but if that assistance could be sifted, coördinated, and supplied in regular shifts to meet ascertained shortages, its value would be incalculably enhanced.

THE VIABILITY OF THE PLAGUE BACILLUS.

THE experience of our Indian plague experts seems to be that the life of the bacillus pestis outside the living animal body is comparatively short, at least under the conditions associated with the climate of India. On the other hand, certain American experts, and among them Dr. Rosenau, express the opinion that the plague bacillus after all is not such a frail organism as was formerly supposed, and that with the help of cold and moisture its life may be prolonged for a considerable period outside the body of an animal host. Given, therefore, abundant albuminous material, a low temperature, and a moist environment, the bacillus pestis may remain viable for a long time. Such conditions presumably might be found when the body of a plague patient has been buried in suitable soil. In the Proceedings of the Medical Association of the Isthmian Canal Zone (Vol. V., Part 2), recently published, a paper is contributed by Dr. H. C. Clark bearing on this subject, and entitled "Note on the Viability of Bacillus Pestis in a Cadaver buried in Quicklime." It appears from this paper that certain excavations were found necessary on Flamenco Island in the Bay of Panama, involving the removal from its grave of the body of a plague patient who had died two years and eight months previously and had been buried in quicklime. The opportunity was taken during the removal of the corpse to ascertain if any living plague bacilli were present in the body. On opening the grave the corpse was found enclosed in lime except where the body rested on the ground, the bottom of the coffin having become disintegrated. The skeleton was perfectly dry, and there was no evidence remaining of visceral tissue or clothing. The skull and femur were selected for special examination. A sterile wire with cotton swab was passed up the foramen magnum and applied to the inner table of the cranial vault, then withdrawn, and agar plates were inoculated from the swab. The condyle of the femur was split and material similarly obtained from the cancellous bone. The agar plates were examined later by Dr. L. B. Bates, bacteriologist to the Ancon Board of Health, who reported that the cultures showed a variety of bacteria, yeasts, and moulds, and that guinea-pigs inoculated with the material had remained in good health. The results were, therefore, entirely negative. Dr. Clark is of opinion that though the amount of material infected by plague bacilli in this body was originally large, yet no trace of it remained at the end of two years and eight months. Probably the corpse might have been removed from its grave at a much earlier period without danger to anyone. No doubt, as he says, the saprophytic organisms greatly aided the quicklime in destroying the plague bacilli. It appears to us that the results observed in this instance were only such as might have been expected, for the experiments in this country of Klein and others have shown that with the advance of putrefaction in a corpse all non-sporing pathogenic organisms are quickly destroyed, even the most persistent of them disappearing within a few weeks.

FRENCH OBSERVATIONS ON THE EFFECTS OF THE IRRITANT GASES USED BY THE GERMANS.

At a meeting of the Académie de Médecine of Paris Dr. R. D. de la Rivière, of the Institut Pasteur, and Professor J. Leclercq, of Lille, have now made an important pathological report on the effects of the irritant gases—chlorine and bromine—used by the Germans. Its interest is increased by observations that so far have not been recorded by our army surgeons. Our *confrères* had under observation in hospital at Calais 112 soldiers who had been exposed to gas at Langhemarck. As the distance from the fighting line is short they were able to examine the patients a few hours after the intoxication. The irritation of the respiratory mucous membrane caused abundant expectoration which was soon tinged with blood. Those who could not fly died vomiting blood. Others, much prostrated, crawled to the rear vomiting and expectorating blood, and they passed bloody urine. On admission to hospital the eyes were watering and the eyelids were swollen. The cheeks and lips were violaceous red, the lips were violaceous, the features were drawn, and the nose was pinched. The patients were harassed by dyspnœa and incessant cough. Some complained of a stitch in the side. There was abundant rosy frothy expectoration, sometimes frankly bloody. Speech was painful and jerky. The majority of the patients presented symptoms of inflammation of the whole respiratory tract extending to the finest bronchial tubes. In these the condition was not grave. But in others the pulmonary lesion was severe and took the form of broncho-pneumonia or gangrene of the lungs. Two patients presented the phenomena of hæmolytic icterus. Another showed hæmoglobinuria for several days. Several had persistent albuminuria. Most of the patients passed concentrated high-coloured urine containing much biliary pigment. At the onset the sputum was characterised by desquamative elements and some polynuclear cells, but soon it was modified so as to indicate congestion and, in some cases, gangrene of the lung. At the onset the microbial flora in the sputum was ordinary, but sometimes anaerobes were found, the bacillus perfringens in particular. In the cases of gangrene of the lung the microbial flora was rich in anaerobes (bacillus perfringens, bacillus serpens, and bacillus ramosus). The findings in a necropsy in a case of death from pneumonia confirmed the conclusions drawn from the clinical phenomena. There were congestion of the whole respiratory tract, injection of the digestive tube, and massive degeneration of the liver, spleen, and kidneys. Massive pneumonia of the right lung, with gangrene here and there at the base, was also found.

THE TREATMENT OF RICKETS.

Dr. Giuseppe Carpani, from his pathological and clinical researches published recently in *Il Morgagni*, has formed the opinion that rickets is a disease of bony development, and that four glands—thymus, thyroid, pituitary, and adrenal—have a marked stimulant and regulating influence over this development. Any one of these glands may be deficient in its function and produce a dystrophic condition which predisposes to rickets. Owing to the correlation existing between these endocrinic glands, a disturbance of function in one of them causes disturbance of function in the others, so that the complex dystrophic picture is the result of failure in function of the entire group. Hence, the indication is to substitute pluriglandular for uniglandular opotherapy, which has hitherto given somewhat favourable but inconstant results. The author gave powdered and dried gland substances *in toto*, in doses suitable to age, in milk daily for 50 days, with the omission of one week after the first month. He noticed that improvement was generally rapid and striking during the first weeks of the treatment, the functions of digestion and assimilation being first influenced, then those of the nervous system. In the following weeks the progress was slower, and beneficial results were observed in the blood and osseous system. The treatment was always well borne. An interesting point observed by the author was that in the cases of children to whom calcium salts were administered at the same time no special rapidity or efficacy of cure was seen, a fact of some importance as bearing on the question of the calcium content in rickety bones, the fundamental fact seeming to be not deficiency of calcium but inability of the tissues to fix it.

THE MARRIAGE OF LEPERS.

The Russian Medical Council has considered the question raised by the Holy Synod of the permission to lepers to marry amongst themselves, and has given the opinion that whilst lepers may not be married to healthy mates there is no objection to lepers marrying lepers. The Council thinks that in respect to the possible influence of the leprosy of the parents on their children in the spread of the disease the factor is relatively weak; besides, the birth-rate in such cases is very low, and the percentage of infant leprosy under such conditions is very small—about 5. With that reply we are in agreement generally. There can be little doubt that the best way of isolating lepers in affected countries is to intern them, under proper medical supervision, in special colonies or settlements where they can, as far as is practicable, lead active and useful lives, engaged in farming and other suitable occupations. Leper asylums and such institutions are best reserved for cases of old and advanced disease where incapacity for employment has been brought about by the ravages of the malady. In the leper colonies or settlements patients of both sexes have to be isolated, and we would raise no objection under certain conditions to the union of these persons if they desired to marry. Young leprous adults of both sexes are more likely to become more hopeful, contented with their lot, if they have a home of their own and a family life, even of a limited extent. The fertility of leper marriages is not great, and as the leprosy advances impotence usually develops. It is imperative, however, that arrangements should be made in advance, and the reasons carefully explained beforehand to the leprous parents, to remove at once any newly born infant from the custody of its mother to a distant home provided by the authorities where the child may grow up without danger of acquiring the infection from its maternal parent. Leprosy is not believed to be a hereditary disease, but close and intimate contact, such as that between a mother and child, is regarded as affording the surest means of conveying the infection from one person to another. We freely admit that the parting of the leprous mother from her newly born child would be painful to her, but in the interests of the child such parting is absolutely necessary and should be regarded as inevitable by both parents. The lot of the leper is admittedly a hard one, and whatever can be done, consistent with medical knowledge and science, should be done in order to alleviate as far as possible the hardships of these unhappy sufferers. With the indicated reservations, we agree with the Russian Medical Council in their view that the marriage of one leprous person with another is, under certain circumstances, permissible.

PNEUMOCOCCÆMIA.

Septicæmia due to the diplococcus has lately assumed a new importance in human pathology, and Banti's idea that the pulmonary localisation might be due to the fixation of the circulating micro-organism by some predilection of the lung is acquiring more and more force and consistency with truth. Dr. T. Pontano has just published in *Il Policlinico* three very interesting cases bearing on this subject. Without going so far as to affirm absolutely that the diplococcus always enters the circulation in the first instance and that a condition of septicæmia always accompanies the pneumonia, the author considers that these cases show that the diplococcus can enter the circulation by little heeded routes such as the tonsils or lesions of mucous membrane, without leaving any trace of its passage, and may cause septicæmia with pulmonary localisation, or sparing the lung, with other local manifestations. The clinical features of diplococcic septicæmia do not differ from those of the ordinary forms, but two are worthy of special attention—namely, the intermittence of the fever with rigors and sweating, similar to suppurative fever, and the intense leucocytosis. The first of Dr. Pontano's cases is the most interesting. There had been an attack of lobar pneumonia a year previously, and the symptoms were those of a pseudo-tetanus, painful contractions of the muscles of the vertebral column, trunk, and limbs, with Kernig's sign; there was also a general febrile condition. The cerebro-spinal fluid was sterile, but a lanceolate capsulated diplococcus was cultivated from the blood which proved fatal to rabbits. Another case described by him was one of purulent meningitis with thrombotic endocarditis in which an identical micro-organism was cultivated from the blood. The lungs were normal.

ACIDOSIS IN CHILDREN.

It is suggested that Naunyn was the first to associate the symptoms of acidosis with their cause, an altered metabolism leading to definite blood changes. That the entity of acidosis is a very real clinical condition especially in children has been recently emphasised by Dr. A. A. Howard in a valuable paper in the *Boston Medical and Surgical Journal*. It is generally supposed to be related to the cyclical vomiting in children, but Dr. Howard suggests that this latter condition is extremely rare in absence of certain reasonably definite and immediate predisposing causes. He rather suggests, it seems, that certain children are predisposed to the condition of acidosis, and are at times especially susceptible to the train of symptoms it causes. Usually an immediate exciting cause for acidosis is present, and an acute infection is the most frequent of these causes. It is necessary to distinguish the clinical cases of acidosis from those which merely show the presence of acetone or diacetic acid in the urine, for this latter phenomenon is not uncommon. Acidosis is perhaps commoner in the children of the upper and middle classes. Boys and girls seem equally liable. It is as common below the age of 2 as above. The symptoms are often ushered in by premonitory loss of appetite, restlessness, or irritability. Constipation at this stage is frequent. Then the mouth becomes dry, acetone appears in the breath, and may be demonstrated in the urine. The respiration is rapid and there may be nausea or vomiting. Vomiting was a symptom, usually an early one, in 51 out of 64 of Dr. Howard's cases. It is significant to note, too, that in the 13 cases in which no vomiting occurred treatment directed to the acidosis had been begun early. In severe cases of acidosis the child passes on to listlessness and drowsiness, the eyes become sunken, and the breathing may become irregular and Cheyne-Stokes like in type. There were 3 fatal cases in the series of 64. The clinical impression in many of these cases is that of a degree of illness and exhaustion which cannot be accounted for by the local signs or known lesion present. It is important to recognise the condition, as treatment directed to its relief may be life-saving in certain circumstances. Sodium bicarbonate given, alternately with glucose, by mouth is the best measure. Even if nausea be present, after one or two attempts the patient can usually retain the drug given in this way. The effects of this treatment are eminently good and often rapid in action. All food must be stopped and return to it should not be uselessly hurried. The need for seeking the presence of diacetic acid or acetone in the urine in cases of this kind is obvious in its important relationship to treatment.

MALARIA ARISING IN A NON-MALARIAL DISTRICT.

In the *Medical Journal of Australia* Dr. Sydney Jamieson has reported a case of considerable importance, as it shows the possibility of malaria arising in a non-malarial district. A "scrub cutter and cleaner," aged 58 years, working in the Gosford district of New South Wales, was admitted into Sydney Hospital on Jan. 5th, 1915, complaining of headache, shivering attacks, and lassitude for ten days. He was born in Somersetshire, England. In 1880 he left Plymouth by a sailing vessel for Sydney, where he arrived without having touched at any other port. He worked as a labourer in the Parramatta district. In 1884 he went to Broken Hill *viâ* Port Pirie and after two months returned to Sydney; since that time he had lived in New South Wales. For 30 years he had been subject to slight cough. On examination he looked pale and cachectic. At the bases of the lungs a few high-pitched rhonchi were heard. The spleen was not enlarged. On the day after admission the temperature rose to 102·8° F. at 8 P.M., but fell almost to normal after four hours. On the following afternoon it rose to 104·8° at 4 P.M., but at midnight had fallen to 97·8°. On every other day during the next fortnight the temperature rose in the same way, ranging from 101·5° to 104°. The attacks were associated with headache and shivering and ended in profuse perspiration. They showed an unmistakable resemblance to simple tertian malaria, though the patient had never resided in a malarial district. On Jan. 8th the blood was examined and gave a leucocyte count of 10,125 and a negative Widal reaction. In the sputum the prevailing organism was the staphylococcus aureus, and there were no tubercle bacilli. On Jan. 12th a careful search was made for the plasmodium malariæ in the blood without result, but on the 18th the tertian type of organism was found in considerable numbers. The disease quickly yielded to quinine. Both the anopheles and the stegomyia mosquitoes are present in New South Wales, but no case of malaria of local origin appears to have been reported previously. It is known that infected mosquitoes can convey the plasmodium malariæ in non-malarial climates. The classical experiment in which Sir Patrick Manson's son infected himself in London by means of a mosquito brought from Rome showed this. Mosquitoes do not appear to travel very far, but in exceptional instances may be carried long distances by ships and trains. A considerable number of soldiers infected with malaria have returned to Australia from New Guinea, but the patient had never been brought into contact with any of them. Dr. Jamieson suggests the possibility of malaria becoming endemic in Australia.

BRITISH PHARMACEUTICAL CONFERENCE.

THE annual meeting of the British Pharmaceutical Conference will be held at 17, Bloomsbury-square, London, on July 14th, under the presidency of Captain E. Saville Peck, M.A. In view of the fact that the majority of members of the Conference are directly or indirectly engaged in the prosecution of the war, the Executive Committee has decided to abandon entirely the social side of the meeting, and also to hold no meetings of the Science and Practice Sections. It may be remembered that in the ordinary course of things the annual meeting would have been held at Scarborough.

FALSE LOCALISING SIGNS IN CASES OF CEREBRAL TUMOUR.

THE practitioner familiar with the classical triad of symptoms—headache, vomiting, and optic neuritis—characteristic of cerebral tumour, should be on the look-out for cases where one or other or all of these symptoms may be wanting. They may fail, for instance, in progressive hemiplegia—i.e., in hemiplegia which is mild in degree at first and becomes progressively more serious; here the clinical type suggests increasing pressure by itself, whatever other signs are present or absent. Again, Jacksonian epilepsy is a suspicious symptom, though it occur monosymptomatically. Once more, a fair number of cases originally diagnosed as idiopathic epilepsy turn out eventually to be cases of cerebral tumour. It behoves the physician, therefore, to keep such cases under close and repeated observation, for as the disease progresses the diagnosis may have to be reconsidered. There is another type of case, however, where a diagnosis of intracranial neoplasm is correctly made, but where the localising, or rather the apparent localising, symptoms are misleading. Surgical intervention depends for its success on correct localisation, but even the expert is occasionally at fault in his localising diagnosis. Some types may briefly be mentioned. It is a fairly common experience to find frontal tumours with cerebellar signs and *vice versâ*. As a rule in such cases, also, right frontal tumours are diagnosed as left cerebellar and left as right. A probable explanation is that with increase of intracranial pressure there is a tendency for part of the cerebellum to be pushed into the foramen magnum, whence cerebellar pressure symptoms readily arise, and these may obscure the frontal symptoms inasmuch as the latter may be slight and not easy of detection. In any case of intracranial tumour, it should be remembered, indirect cerebellar symptoms may be present; and cases of temporal lobe tumour, for instance, have been recorded where the supposed pathognomonic cerebellar tests elaborated by Bárány have been positive. Another type of false localising signs is that where Jacksonian epilepsy is an indirect and not a direct symptom. Even strictly motor symptoms may mislead. Various instances have been put on record of Jacksonian fits arising from stimuli originating outside the motor area proper. In some cases where internal hydrocephalus results from a basal or subtentorial tumour motor symptoms may be present which are secondary and indirect, and therefore apt to confuse. Again, paresis or paralysis of one or other external rectus is probably of little localising value by itself, as in almost any case of subtentorial tumour, and in some supratentorial cases too, the symptom may signify only a heightened intracranial pressure and nothing more. In fact, it is well never to lose sight of the obvious fact that if a foreign body grows within the cranial cavity it can only do so at the expense of other tissues, and such secondary changes as local evascularisation, œdema, ventricular dilatation, pressure of one or other part of the cranial contents against some bony prominence or into some bony ring may effectually mask the actual lesion and lead to erroneous localisation. For this reason minute attention should always be devoted to the earliest symptoms in point of time, however slight or transient they may seem to have been, since they, rather than any of the more prominent but subsequent ones, may really point to the exact site of the disease. Another reason is that there may be a direct transference of functional disturbance from one part of a linked physiological system to another through the medium of so-called diaschisis, whereby, apart from extraneous causes such as have been enumerated above, symptoms are produced in one area, the morbid condition giving rise to which is, in fact, situated in a different, though physiologically connected, area. Thus in some cases of tumour of the motor cortex, with Jacksonian epilepsy, twitching of the corresponding muscular groups homolateral to the lesion has been noted, by diaschisis from the affected motor area to the motor cortex of the opposite hemisphere. Some of these and other important considerations in the diagnosis of cerebral tumours are well illustrated in a series of cases carefully observed by Dr. S. P. Goodhart and Dr. H. Climenko, of the Montefiore Home and Hospital, New York, and published by them in the April number of the *Journal of Nervous and Mental Disease*.

AN Order in Council, dated June 10th, declares that the Province of Saskatchewan, in the Dominion of Canada, shall be deemed a separate British possession, and that the second part of the Medical Act, 1886, shall be deemed as from the date of the Order to apply to the said Province of Saskatchewan. The effect of this is to render medical degrees of that province under certain conditions registrable without examination in the colonial part of the Medical Register.

Dispensary Doctors as "Medical Advisers."

THERE is no doubt that a good deal of inconvenience to the sick poor has arisen from the fact of certain dispensary medical officers accepting the office of "medical adviser" to the Insurance Commissioners. The duties of the office entail travelling over wide areas, whereas dispensary medical officers are not allowed to leave their districts even for a day without making provision for the discharge of their duties. It is impossible for those who are medical advisers to make such arrangements since the profession disapproves of the office, and those who hold it are not assisted in any way by their medical neighbours. Some boards of guardians also have considered that the Poor-law duties have been neglected by the officers who are medical advisers, and have proposed to dismiss them from their appointments as Poor-law officers, but up to the present the Local Government Board has not sanctioned such action. Recently, however, a war vacancy having occurred in the Poor-law service of the Newry union, the guardians appointed Dr. T. Cronin as temporary medical officer. The Local Government Board has declined to sanction the appointment on the ground that Dr. Cronin is a "medical certifier" to the Insurance Commissioners, and that "the Board is not satisfied that he could attend efficiently to the wants of the sick poor" of the district.

A Students' Strike.

A certain number of the students at the school of the Royal College of Surgeons in Ireland struck work last week, as far as the department of anatomy was concerned, as a protest against the choice of the Council in the recent election of examiners in anatomy. It is usual for the professor of anatomy to be one of the examiners, but this year the professor is absent on military duty, and the students took umbrage at the fact that his deputy was not elected examiner. After a few days' abstention from work the students returned, pending the Council's considering their protest. The Council can hardly assent to the position that the election of examiners should be subject to veto by the prospective candidates.

The War Office and the Belfast Scheme for a Base Hospital.

A number of Irish medical men, mainly colleagues hailing from Belfast and its immediate vicinity, and, numbering some well-known surgeons, physicians pathologists, and sanitarians, recently appealed to the Director-General of the Army Medical Department to be allowed to staff a base or stationary hospital at the front. The offer was that for periods of six months they would work as a band and succeed each other in relays of, say, 20 to 25 men at a time for half a year. In this way the War Office would acquire, they suggested, the help of some of the most experienced surgeons in Ireland, over military age, who, by manning a base hospital, would free younger men for other work. The War Office has been compelled to refuse this patriotic offer, as there are no regulations in force to enable it to be accepted or worked. The reply of the War Office is much resented in Belfast. As Mr. Lloyd George recently said at a public meeting in Liverpool, "In this tremendous crisis of the empire there is one thing we want less of than usual, and that is red tape. It takes such a long time to unwind and we can't spare the time."

Ulster Medical Society.

At the annual meeting of the Ulster Medical Society, held in the Medical Institute, Belfast, the following were elected office-bearers for the session 1915–16:—President: Dr. A. G. Robb. Vice-Presidents: Mr. T. A. Davidson and Dr. W. E. Hadden (Portadown). Treasurer: Dr. V. G. L. Fielden. Librarian: Dr. W. L. Storey. Secretary: Mr. S. T. Irwin. Editorial Secretary: Dr. C. G. Lowry. Council: Dr. G. A. Hicks, Mr. J. O'Doherty, Dr. J. C. Rankin, Dr. J. L. Rentoul (Lisburn), Dr. F. C. Smyth, and Mr. H. Stevenson.

The McQuitty Memorial Exhibition.

The McQuitty Memorial Exhibition, given for clinical work to senior students attending the Royal Victoria Hospital, has been awarded to Mr. E. G. B. Calvert.

June 15th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

A Hostel for Disabled Sailors and Soldiers.

AN urgent appeal for help for the crippled men discharged from navy and army hospitals has gone out in Scotland. These men are not infrequently under the necessity of returning to their homes, where they cannot have advice or help to equip them for the future. It is proposed to keep the crippled and disabled men at a hostel until they are fit for employment, and then to send them to the various institutions where they can be taught trades of suitable kinds. Edenhall, Kelso, has, through the kindness of Major Douglas, been taken for the purpose of a hostel, and will accommodate from 35 to 40 patients. By permission of the Berwickshire county directors, the hostel will be worked by the Coldstream Voluntary Aid Detachment under a fully trained nurse. As the hostel will be supported by voluntary subscriptions help is earnestly requested, and subscriptions should be sent to the treasurer, Mr. Douglas, Mansfield, Coldstream. All information regarding the hostel and admittance of patients will be given by Lady Isobel Douglas Home, The Horset, Coldstream, who has issued the appeal. Surgeon-General G. D. Bourke, Deputy Director of the Army Medical Service, has given this scheme his support.

The Edinburgh Academical Club.

The annual general meeting of the Edinburgh Academical Club was held in Dowell's Rooms, Edinburgh, on Friday, June 11th. The Right Hon. Sir J. H. A. Macdonald, K.C.B., Lord Justice Clerk, President of the club, presided. The chairman, in moving the adoption of the annual report, referred to various matters dealt with. He said that about 800 Academicals had been serving the King in various capacities since the outbreak of war, and of these over 40 had been killed in action. The club has raised £1200 for a motor ambulance fund, and two ambulances of the latest War Office design, which were nearly ready for sending to the front, have been presented to the Scottish Branch of the British Red Cross Society.

An Ambulance Car from Linlithgowshire.

Under the supervision of ex-Provost Gordon, Bathgate, the inhabitants of Linlithgowshire recently subscribed towards the purchase of an ambulance motor-car for the use of the wounded soldiers at the front. On the afternoon of Wednesday, June 9th, the vehicle, a 16 h.p. Wolseley, with stretchers and fittings complete, was handed over to the Scottish Branch of the British Red Cross Society at 11, Blythswood-square, Glasgow, the headquarters of the Scottish Automobile Fleet. After the purchase of the car there was a balance of nearly £80, which was presented to the British Red Cross Society.

The Fire at Dunrobin Castle.

The modern portion of Dunrobin Castle, the Duke of Sutherland's famous Scottish palace, was largely destroyed by fire on June 13th. In the difficult task of combating the flames valuable assistance was rendered by Territorials who were in the neighbourhood, and also by a fire brigade section of the navy from Cromarty. All the wounded soldiers were rescued and removed in safety to accommodation that was found for them elsewhere. Unfortunately in the work of rescue Lieutenant Wilde, 2/5th Seaforth Highlanders, and two sailors were seriously injured and had to be removed to hospital.

The late Dr. E. W. Scott Carmichael.

The death occurred on June 12th, at his residence, 42, Palmerston-place, Edinburgh, of Edward William Scott Carmichael, Fellow of the Royal College of Surgeons, Edinburgh. Dr. Carmichael, who was in his forty-second year, came of a well-known medical family, for his father, Dr. James Carmichael, is a consulting physician to the Royal Hospital for Sick Children, and his grandfather was a much esteemed Edinburgh practitioner. Dr. Edward Carmichael was educated at the Edinburgh Academy and the University of Edinburgh. He studied subsequently in Berne, Berlin, Greifswald, London, Paris, and the United States. He was formerly senior demonstrator of anatomy in the New School of Medicine and assistant surgeon at the Royal Hospital for Sick Children, Edinburgh, at the Royal Infirmary, and at the Hospital for Diseases of Women. He also held the rank of captain in the 2nd Scottish General Hospital, Territorial Force. Dr. Carmichael was a frequent contributor of articles to the medical press. His literary work was stamped with scientific thoroughness, and it is to be hoped that the book upon which he had spent several years of work, and succeeded in completing only a week or two ago, will be published. He was an admirable speaker, and had the ability to inspire confidence in those who heard him. He leaves a widow and three young children.

The late Lieutenant D. G. Watson.

Lieutenant D. G. Watson, R.A.M.C., who has died of wounds received while on active service at the front, was the son of Mr. John Watson, B.A., headmaster of Broughton Higher Grade School, Edinburgh. He was a graduate of the University of Edinburgh in both Arts and Medicine. After graduating in Medicine Dr. Watson was appointed to a hospital at Windsor, and on the outbreak of war he joined the Royal Army Medical Corps. He had been at the front for several months, and when wounded was engaged in bringing in a stretcher party from one of the trenches under shell fire.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Substitution of Hot Oxygen for Hot Air in the Sterilisation of Gangrenous Wounds.

M. Vignat has endeavoured to replace hot air by superheated oxygen in a large number of cases of septic gangrene following on deep charring. He considers this procedure superior to that of hot air. Its technique is very simple. An ordinary electric apparatus is used, and the source of air represented by the rotary pump is replaced by a cylinder furnished with a stop-cock. The current of oxygen can be regulated at will by means of this stop-cock. Certain precautions are necessary. The oxygen should never be used with Gaiffe's apparatus, as the oxygen produces with carburetted air an explosive mixture. In the passage of oxygen the generator of heat becomes heated more quickly, and in order not to damage it the rheostat which regulates the current intensity should be handled gently and progressively. It is necessary to be careful that the field in which compresses are situated in the neighbourhood of wounds is moist, as the action of the superheated oxygen is inflammatory. Oxygen seems to dry and sterilise moist gangrene better and more quickly than air. The action of heat is added to the action of the oxygen and also to the ozone which is produced, as is known, whenever oxygen is superheated.

The Destruction of Lice in Epidemics of Typhus Fever.

Dr. Delta, in the past Balkan campaigns, had frequent occasion to believe that the action of strong odours was destructive to lice, and he undertook numerous experiments on this subject. Living lice were put in the cavity of a piece of glass tubing 2 centimetres in diameter and 15 centimetres in length, plugged by means of two cotton wads loose enough to allow the circulation of air. On moistening one of the two wads with strong scent the insects withdrew little by little from the perfumed end and approached the opposite one. At the end of a certain time all the lice were dead. If the source of the odour was placed outside one of the corks the same phenomena were observed, followed by death, though naturally after a much longer time. In the control tubes in which the perfume was replaced by water, the lice remained alive moving freely in all directions. In another experiment a large tampon of cotton soaked with strong perfume was placed in the bottom of an upturned microscope shade. Above this tampon, but separated from it by a tripod of iron wire, was a piece of flannel a yard square, in the folds of which were a known number of living lice. At the end of a quarter of an hour, on the average of four experiments, the first louse was seen to emerge from the folds of the cloth and struggle to reach the open air. At the end of an hour four others disengaged themselves in like manner and remained on the surface without attempting to penetrate again into the interior, where the ten other insects were found motionless. Left in the open air four of them returned to life after a variable period of time. Finally it was shown that when the contact of the perfume and of the insect was made directly, the result was not long in being produced. The insect died in one or two minutes. In a recent epidemic of typhus fever at Alexandria in February, 1915, two distinct foci appeared, one in a camp of Bedouins in the desert, the other in the very centre of the town. Among the Bedouins were counted in all 96 cases and 52 in the town. The disease was attacked by the ordinary methods of disinfection of the locality and of articles of bedding and clothing. And here, too, the procedure of perfumed lotions was put into practice in a systematic fashion, and to bring out its advantage more clearly, washing with hot water and soap was foregone, washing from head to foot with eau de Cologne locally manufactured and of poor quality, but emitting a very powerful and persistent aroma alone being practised. Then the epidemic ceased. It is evident that these observations cannot definitely prove the efficaciousness of perfumed lotions, but the procedure is new and deserves at least a trial.

The Treatment of Large Wounds by Sterilised Sugared Radio-active Mud.

Dr. Gougerot has obtained good results in the treatment of wounds and intractable ulcers by the use of a mixture of radio-active mud with sugar. This treatment is simple and inexpensive. The radio-active mud is sold commercially in boxes containing a kilogramme. This mud is diluted with water saturated either with white sugar (saccharum) or glucose, so as to make a thick though fluid paste. It is sterilised in little bulbs in the autoclave at a temperature of from 100° to 110° C. The wound having been washed with boiled water or sugared water, is coated with a thick layer of the mixture and covered with an aseptic compress that has been sterilised in the autoclave, and is then dressed in the ordinary way. If possible the wound is left three, four, or six days without changing the dressing, which is removed by moistening the compresses with boiled water. It is washed to remove the mud and a fresh mud dressing applied. The mud which has been used may be recovered by filtering the wash water through blotting-paper and cloth and by sterilising it afresh. The radio-active mud causes stimulation of torpid tissues; the sugar supplies nourishment to them. The ulcers usually granulate (*bourgeonnent*) rapidly, the wound becomes red, vivid, often very congested. This treatment should be applied especially to the cicatrisation of large superficial or deep wounds like those of varicose ulcers, but should not be applied to fistulous ones in which suppuration is maintained by foreign bodies or foci of osteitis. It is necessary first to suppress these causes and then the dressings of sugared radio-active mud begin their utility in promoting cicatrisation.

Protection of the Skull against Wounds by a Metallic Headpiece.

M. Le Dentu and M. Devraigne drew the attention of the Academy of Medicine, at the first June meeting, to the use of a metallic headpiece as a preservative against wounds of the head. Such wounds have become very frequent and represent 13·33 per cent. of all wounds. The personal observations of M. Devraigne clearly establish the advantage to the soldiers of wearing metallic headpieces. Out of 55 soldiers hit in the head and treated by M. Devraigne, 42 were without such headpieces and 13 possessed one. Of the 42 soldiers without, 23 suffered fractures which for the most part were followed by death, and 19 presented wounds of the head and scalp. Of the soldiers belonging to the second group 5 had simple superficial wounds or scratches or suffered no harm at all.

June 14th.

THE BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND.

NEED FOR SURGICAL INSTRUMENTS IN BELGIUM.

THE information received from the Aide et Protection aux Médecins et Pharmaciens Belges Sinistrés to the effect that a further supply of surgical instruments would be useful in Belgium has now been confirmed by the National Relief Commission, and the British Fund is preparing to send through the offices of that commission a large supply of surgical instruments to Brussels. The response to the invitation to supply instruments, which has appeared at different times in these columns, has been very good, but further heavy demands upon the stock in hand would soon deplete it. We are therefore renewing the public request for instruments which for a time has ceased to appear, owing to the response seeming to meet the needs of the time. Mr. Meredith Townsend, Master of the Society of Apothecaries of London, has personally supervised the packing of a further consignment to Belgium, and all the instruments to be sent are of modern type and have been repaired in every way.

THE WEEK'S SUBSCRIPTIONS.

The week's subscriptions include a further contribution from the North of England Branch Fund, a most energetic body, and a handsome subscription of £168 from New Zealand.

THE APPEAL FOR SURGICAL INSTRUMENTS.

The Master of the Society of Apothecaries will receive and acknowledge with thanks any surgical instruments which are sent to the Apothecaries' Hall, Blackfriars, E.C.

DONATIONS AND BEQUESTS.—By will the late Dr. W. T. Edwards, of Cardiff, left £500 each to the Royal Medical College, Epsom, and the Medical Benevolent Fund. In the event of the failure of certain trusts the testator bequeathed £7000 to the University College, South Wales and Monmouthshire, towards the maintenance of the Medical School; £6000 to the King Edward VII. Hospital, Glamorganshire; and £1000 to the Blind Asylum or Workshop, Cardiff.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE undermentioned have been granted temporary commissions as Surgeons in His Majesty's Fleet: Hother McCormack Hanschell and Arthur Toulmin.

The following appointments have been notified:—Fleet-Surgeons: R. W. Stanistreet to the *Endymion*; S. Conner to the *Theseus*; and E. D. J. O'Malley to the *Maidstone*. Staff-Surgeon: J. Thornhill to the *Victorian*. Temporary Surgeons: W. H. Kay to the *Theseus*; and S. N. Toulmin to the *Endymion*.

ARMY MEDICAL SERVICE.

Colonel Sir B. G. A. Moynihan relinquishes his temporary commission (dated Feb. 28th).

ROYAL ARMY MEDICAL CORPS.

The undermentioned Majors to be temporary Lieutenant-Colonels: William A. Turner, R.A.M.C. (T.) (dated May 26th), and Charters James Symonds, R.A.M.C. (T.) (dated June 1st).

Major Robert H. Mills-Roberts, C.M.G., 6th Battalion, The Royal Welsh Fusiliers, to be temporary Lieutenant-Colonel whilst employed with a Field Ambulance of the 43rd Division (dated Dec. 2nd, 1914).

Theodore Mailler Kendall, late Fleet Surgeon, Australian Navy, to be temporary Major (dated May 17th).

The undermentioned are granted the temporary rank of Major whilst employed at the Welsh Metropolitan War Hospital:—Dated May 1st: Edward Barton Cartwright White. Dated June 2nd: Howard Davidson Harrison and Charles Henry Geoffrey Ramsbottom.

Major Arthur Nimmo Walker, 1st West Lancashire Brigade, Royal Field Artillery, Territorial Force, to be temporary Major (dated May 22nd).

Temporary Captain Edward L. Gowlland, late Major, Royal Garrison Artillery (T.), to be temporary Major (dated June 11th).

The undermentioned to be temporary Captains: Dated May 3rd: Denis Murphy, late Captain, R.A.M.C. (Special Reserve), and Frank Alfred Amphlett Holmden, D.S.O. Dated May 6th: William John Gow. Dated May 7th: Ralph Bodkin 'Mahon. Dated May 14th: Thomas Watts Eden. Dated May 15th: Victor John Blake.

Temporary Lieutenant Percival Wood, late Surgeon-Captain, 3rd Middlesex Royal Garrison Volunteer Artillery, to be temporary Captain (dated June 15th).

Arthur Conyers Inman to be temporary Honorary Lieutenant (dated June 3rd).

The appointment to a temporary Lieutenancy of George H. Wood is antedated to April 13th.

The undermentioned temporary Lieutenants relinquish their commissions:—Dated May 14th: R. F. Ferris. Dated June 1st: James J. Keirans.

Temporary Lieutenant Ernest C. Peake relinquishes his commission on account of ill-health (dated May 21st).

The undermentioned to be temporary Lieutenants:—Dated Nov. 24th, 1914: Walter Amsden. Dated April 24th: Lieutenant James Burgess Woodrow, Canadian Army Medical Corps. Dated May 1st: Conrade Loddges. Dated May 3rd: Alfred Adams, Robert Ferguson Russell, Mark Stewart Fraser, Gerald Holroyde, Dallas Gordon Perry, Thomas Ewart Ashley, William Russell, Francis George Macneill Simpson, Rowland Hamer, Henry Edwardes Griffiths, Richard Walton Long, and Edward Thomas Larkam. Dated May 4th: William Harrison MacKinlay, Cyril Rodney Holtz Crawford, Ernest Camden Pratt, Alic Phillips, Robert James Bonis, Arthur Hamilton Tovey, James Richardson Spensley, Henry Murray Agnew, George Gardner, Andrew Walker Forrest, John Bruce Baird, and John Dorrington Batt. Dated May 5th: Robert Spears, John Frederick Broughton, Wyger Harmens, Guy Nasmith Mottram, and Jocelyn Langton Waller. Dated May 6th: John James Robertson, Charles Broderick Pearson, Hugh Hadfield Carleton, and Stephen Frederick Lynch. Dated May 7th: William Fraser, Ernest Goodwin Rawlinson, Daniel Kelly, Edward John Morton, Edwin Arthur Cleveland Swainson, Cecil Bennett, Charles Samson Thomson, John William Innes, Benjamin Jones, Robert Reid Pirrie, Leo Lane, Donald McFarlane Livingstone, John Wilson McCagie, John Brownlee Milne, Frank Barney Gorton Stableford, Thomas Geoffrey Elsworth, Gerald Sholto Douglas, John Pole Kitson, Patrick Joseph Murphy, Ernest Haines Walker, Mearns Alexander Milne, James Coutts, Anthony John McCreadie, George Miller, Robert MacNab Marshall, Harold Webb, Charles Leslie Grove Powell, James Muirhead, Joseph Bernard Dawson, Herbert Maughan Brown, Augustus Joseph Hickey, Richard Hubert Mercer, Robert Reid Duncan, Noel Instone, Andrew Serjeant McNeil, Ernest Theophilus Roberts, Ronald John Bruce, and Joseph Michael Morrissey. Dated May 8th: Philip Cyril Powter Cloake, George Norman, Charles Putnam Symonds, Archibald Guelph Holdsworth Smart, Henry François Vandermin, Albert William Duncan Coventon, and Ernest George Douglas Pineo. Dated May 9th: Percy Knowles Muspratt. Dated May 10th: Guy Alfred Wyon, Sydney Charles Hillyard Moberley, Denis Gratwicke Halsted, Charles Richard Verling-Brown, Oswin Shields, Henry Yellowlees, John Coffey, Austin Threlfall Nankivell, Richard Henry King, George Pollock, Robert McLaren Wishart, William Wallace Wood, Charles Harold Bloxsome, James Todd Dickson, John Melville Elliot, John Munro Campbell, John Buchanan, D'Arcy Irvine Hamilton, Harold Ernest Pierpoint Yorke, John Miller Young, Kenneth John Aveling, Leopold Ernest Valentine Every-Clayton, George Henry Russell, Sydney Waddell, John Dodds Marshall, Lionel Augustine Joseph Graham, Alexander Bruce Gordon, George Henry Keane, Stanley Victor Percy Pill, James Felton Hammond, William Arthur Anderson, Charles Reidy, John Maxwell Taylor, William Richard Morris, William Patrick Cooney, John Dixon, Frank Radcliffe, Alexander Church Brodie McMurtrie, William Stewart, Harry Tudor Newling, and Howard Ebenezer Collier. Dated May 11th: Harry Lawrence Attwater and Cecil Rutherford. Dated May 12th: George Stoddart, Sidney John Rowntree, James Alexander Wood Watts, Albert Victor Craig, Gordon Wilfred Ritchie Rudkin, Herbert Michael Moran, Clement Kirwan Sylvester, Archibald Ferguson, David Albert Hutcheson, Herbert Bates, Samuel Frederick Holloway, Frank Edward McGee, Edward Irving Pownoll Pellew, William Henry McKinstry, George Amos Varian, Peter Macdonald, William Edward Lindsey Fowler, William Guy Embleton Allen, and Frederick Travinor Rees. Dated May 13th: William James Valentine Curtain, Hugh Arthur Evans, and Howard Stein Millar. Dated May 14th: Percy Hall, Gerald Richard Courtenay Wilson, Richard Hamilton Ashwin, Benjamin Beamish, Alfred Benjamin Bateman, Harry Gordon Leigh Gilchrist, Thomas Mackinlay, William Ross, Arthur Gerald Welsford, William Hastings Hardy, Robert Devereux Mothersole, Colin Charles Gordon Gibson, Norman Gerald Meade, Arthur Daniel Clanchy, Aaron Simeon Cohen, Ignatius Patrick Kelly, Eric Bayley, John Edward Litton Alexander Turnley, John Thomas Armstrong, Berthold Somerville Taylor, and Ronald Tydd Herdman. Dated May 15th: John Hardwick Thornley, Robert Broom, Henry Brown Elton, John Douglas Wilkinson, Sol Cross, Burke Cuppage, Archibald Penrhyn Bowdler, David Thomas Crichton Frew, Alfred John Davoren, Edward Hamilton Bruce Fox, Hight Blundell, Albert Cameron, Andrew Wilson Cochrane, William Ashley Graves Cluffe, Robert Donald, Tom Henry Trevethan Frampton, Francis William Fawssett, James Edgar Hewlett, James McAvoy, Archibald Underwood Millar, Murdo Duncan Mackenzie, Andrew Brown McPherson, Arthur Robert Moore, Thomas McCririck, Willie Oliver, Victor John Ruttledge, Thomas Readman, Francis Riley, Herbert Douglas Smart, Daniel Stewart, David Taylor, William Wilson Wood, Herbert Kidson Wallace, John Wilson, James MacGregor Johnson, John Joseph Pentony, John Newton Martin, Alexander Farquhar, Leonard Owen Weinman, Gilbert Winter Dryland, George Habgood, George Hobson Thompson, Bentley Moore Hunter, Archibald Macmillan, Arthur Henry Thomas, William Francis Blewitt, Frederick George Beatty, Ivon Henry Skipwith Hawes, William Albert Wheeldon, Alfred Whitby, George Wheldale Stanley, and Henry Richard Rigby. Dated May 17th: William Bates, Robert Joseph Weidner, William R. Thomas, James Hamilton Fleming, William Reid, James Alexander MacLaren, William Deane, Alexander Joseph Dempsey, Thomas Bennett, Cecil Lionel Lakin, James William Hutton, Kenneth Gillies, Robert Grant, George William Bennett Waters, James Robert Burn, Burford Noel Norman, Sidney Herbert Booth, Murdo Maclean, Alexander Johnston Wilson, James Joseph Foley, Alfred Robert Sieveking, David Joseph Miller, William Wilson Jameson, John Erwood Forster, Penrose Lanyon Watkin-Williams, Samuel Edgar Martin, Alan Renata Green, Maurice Hereward Cane, Henry John MacKay Adams, Francis James Wheeler, John Carr Osburne, James Maxwell, Horace Bagster Wilson, Edgar James Tyrrell, William Alexander Milne, Joseph Dudley Benjafield, Reginald Power, Frank Davidson Johnson, Albert Ernest Henton, William Robert Honeyburne, William John Gilmour Henderson, Joseph Green, Wilbye Cooper, John Frankland West, Geoffrey Clarke, Lieutenant Alexander Barnett Brook, 4th Battalion, Seaforth Highlanders (Ross-shire Buffs, The Duke of Albany's), Territorial Force. Dated May 18th: John Mandall Coates, David Lawrie, and Cecil William Wilson. Dated May 19th: John Miles Chambers, Robert Hamilton, Herbert Walker Binks, William Doyle, John Anderson, Stanley Batchelor, Alfred Hollier Clough, George John Fraser, Harold Stanley Groves, Lancelot Raoul Lempriere, Robert McLean, George McNeill, Thomas Stanley Rippon, Noel Florentine Rowstron, Algernon Verling, Alexander Sweet Wilson, William

Frederick Rhodes, Norman Tattersall, William Leitrim Clements, Frederick Ernest Chapman, Trevor Hayman Fowler, and Giulio Hamilton.

The undermentioned officers of the Canadian Army Medical Corps to be Temporary Lieutenants: Dated May 10th: Major Norman King Wilson; Captains John Vassie Brown, Robert Werden Tennent, and John Jordon Field; and Lieutenants William Samuel Pickup, William James Morden Marcy, Frank Muir Walker, Herbert Wilfred Kerfoot, John George McLeod, Ernest Victor Frederick, Alfred Hope Macklin, Albert Franklin Mavety. Richard Earl Horkins, George Norman Uric, Ross Lester Shields, John Joseph Middleton, John LeKoy Mavety, James Willis Sutherland, Joseph Austin Evans, Murray Hulme Paterson, Frederick Johnson Livingston, George Chambers Anglin, John Nelson Humphrey, Keith Myrie Benoit Simon, James Franklin McLay, Richard Henry Bonnycastle, Lionel Montrose Dawson, Warren Augustus Dakin, James Edward Knox, Oswald John Day, Kenneth George McKenzie, Victor Howard McWilliams, Frederick James Colling, Henry Crassweller, Oliver William Colbeck, Frank Howard Wheeler, John Harold White, George Walker Manning Smith, Archibald Henderson, Thomas Oswald Hutton, and Charles Goldie Sutherland.

The undermentioned non-commissioned officers and men of the Canadian Army Medical Corps to be temporary Lieutenants:—Dated May 27th: Staff-Sergeants William James Deadman and Samuel Alexander Overend, Sergeants Leeming Anderson Carr and Frank Whiting Overholt, Lance-Corporal John Thomas Courtice, Privates John Chassels and Harry Arthur Cates. Dated May 28th: Staff-Sergeants Duncan Archie Fletcher, George Murray Shaw, and Charles Lennox Tulloch Arthur, Corporal John Victor Williams, Privates Halstead Graime Murray, Charles Havelock MacLean, Harry Adolph Sharman, Wellington Lekoy Pedlow, Otto Van Luven, and Ernest John de Beaupré. Dated May 29th: Sergeant-Major Alfred Clarence Brisco. Dated May 31st: Sergeant Major Walter James Bolt Brown, Sergeant John Francis Ryan, Corporals George Beatty Burwell and Everett Franklin Garfield Ward, Privates Frederick Walter Diamond, David Archibald Macfarlane, Hector McKenzie, Kenneth Earl Millan, Joseph Stokes Stewart, Norman Michael Glace, George Sampson Cronk, John Henry Fisher, Warren Fullerton Clark, John Howard Box, Arthur George Howson, Kenneth Lorne Mackinnon, and Harry Love Jarman.

SPECIAL RESERVE OF OFFICERS.

Royal Army Medical Corps.

Lieutenant Thomas McEwen to be Captain.

The undermentioned Lieutenants (on probation) are confirmed in their rank: Robert McKinlay, Douglas Cran, John O. Reid, William B. Postlethwaite, Patrick C. MacRae, Robert P. S. Mason, Gilbert W. Rose, Neville H. Linzee, Frederick E. Fielden, William B. Cathcart, Raymond F. Pinson, Austin B. Clarke, Alfred T. Logan, James G. Wilson, and John F. Lyons.

TERRITORIAL FORCE.

Army Medical Service.

Major William Cochrane Murray, from 1st Lowland Field Ambulance, to be Deputy Assistant Director of Medical Services, Lowland (Reserve) Division.

Royal Army Medical Corps.

2nd East Anglian Field Ambulance: Lieutenant Frederick G. Sharpe resigns his commission on account of ill health.

3rd Home Counties Field Ambulance: Michael Arthur Curry to be Lieutenant.

South-Eastern Mounted Brigade Field Ambulance: Cholmondeley Webb to be Lieutenant.

2nd West Lancashire Field Ambulance: James Pearson Thierens to be Lieutenant.

2nd Northern General Hospital: James Blacklay Lockerbie to be Captain, whose services will be available on mobilisation.

1st Western General Hospital: Thomas Porter McMurray to be Captain, whose services will be available on mobilisation.

2nd Western General Hospital: Howard Buck to be Captain, whose services will be available on mobilisation. Edward Albert Williams to be Lieutenant.

1st Highland Field Ambulance: Captain Peter Howie to be temporary Major.

5th London Field Ambulance: Captain John Herbert Dixon to be temporary Major.

1st Northumbrian Field Ambulance: Edward Turton (late Captain, 5th (Cyclist) Battalion, The East Yorkshire Regiment), to be Major (temporary).

4th Southern General Hospital: Francis Edward Price to be Captain, whose services will be available on mobilisation.

1st South Midland Mounted Brigade Field Ambulance: Frank Smith to be Lieutenant.

1st Highland Field Ambulance: John Miller Chrystie to be Lieutenant.

3rd West Lancashire Field Ambulance: Bertram Whewell Hogarth (late Major, 5th Battalion, The King's Own (Royal Lancaster Regiment)) to be Major (temporary).

3rd Scottish General Hospital: David Watson to be Captain, whose services will be available on mobilisation.

5th Southern General Hospital: Captain John H. P. Fraser is seconded.

Notts and Derby Mounted Brigade Field Ambulance: Guy Witton Miller to be Lieutenant.

Yorkshire Mounted Brigade Field Ambulance: Charles Graham Meade to be Lieutenant.

1st London (City of London) Field Ambulance: Captain Thomas S. Worboys, from Attached to Units other than Medical Units, to be Captain (temporary). Captain Donald S. Sutherland, from Attached to Units other than Medical Units, to be Captain (temporary).

1st West Riding Field Ambulance: Charles Suffield Brown to be Lieutenant.

2nd West Riding Field Ambulance: Alexander Anderson to be Lieutenant.

3rd West Riding Field Ambulance: William Sneddon to be Lieutenant.

2nd London General Hospital: Captain Maynard Horne is seconded.

1st Northern General Hospital: William Arthur Slater (late Cadet, Durham University Contingent, Senior Division, Officers Training Corps), to be Lieutenant.

1st Scottish General Hospital: Clifford Thiselton Bell to be Captain, whose services will be available on mobilisation. Robert Richards to be Captain, whose services will be available on mobilisation.

1st Southern General Hospital: Thomas Wilson to be Captain, whose services will be available on mobilisation.

2nd London Sanitary Company: To be Lieutenants: James Mair and Alfred Carlton Williams.

Highland Casualty Clearing Station: James McLean Macfarlane to be Lieutenant.

2nd London Casualty Clearing Station: Andrew Tynan Swan to be Lieutenant.

Welsh Casualty Clearing Station: Major Charles R. White, from 2nd Welsh Field Ambulance, to be Lieutenant-Colonel (temporary). Captain Patrick J. McGinn, from 1st Welsh Field Ambulance, to be Captain. The undermentioned to be Lieutenants: Lieutenant John J. E. Biggs and Lieutenant Charles Nyhan, from Attached to Units other than Medical Units, and John Anderson.

Attached to Units other than Medical Units.—To be Majors: Surgeon-Captain James W. Cook, from 5th Battalion, The Lancashire Fusiliers, Captain John Leach, Palemon Best (late Captain, Cornwall (Duke of Cornwall's) Royal Garrison Artillery), and Captain Richard T. Turner. Captain George C. Jeaffreson resigns his commission on account of ill-health. Edmund Percival Isaacs Coke (late Captain, R.A.M.C., Territorial Force) to be Captain (temporary). To be Lieutenants: Charles Cooper Ling, John Wood, and John Ernest Ransford. Captain Lawrence C. V. Hardwicke is restored to the establishment.

DEATHS IN THE SERVICES.

Major Arthur Tregelles Pridham, I.M.S., suddenly, on June 6th. He joined the service in 1902, and in 1911–12 took part in operations in the Abor country (medal with clasp).

Surgeon-General Thomas Grainger, C.B., I.M.S., has been appointed an Honorary Surgeon to the King, vice Surgeon-General G. F. A. Harris, C.S.I., retired.

THE NATIONAL CARE OF MATERNITY.—On June 11th a deputation from the Women's Coöperative Guild waited on Mr. Walter Long, President of the Local Government Board, to urge immediate legislation dealing with the care of maternity and infancy. Mr. Long said that he would be glad to introduce legislation making the Notification of Births Act compulsory all over the country.

THE LATE DR. J. P. CAMERON.—The death of Dr. J. P. Cameron is announced as having taken place on Savage Island on March 13th, where he was medical officer under the New Zealand Government. Dr. Cameron, who was 29 years old, was a Scotsman, and was educated at Aberdeen University, where he graduated as M.B., C.M. in 1910.

NEW BUILDINGS AT THE DURHAM COUNTY HOSPITAL.—On June 12th a new operating theatre and a nurses' hostel were opened in connexion with the Durham County Hospital by the Earl of Durham. Only £560 of the £5320 which the buildings have cost remain to be raised, the Ven. Archdeacon Watkins and his wife having given £1000 towards the theatre, and Miss Margaret Brown, of Durham, having made herself responsible for the hostel.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN the 96 English and Welsh towns with populations exceeding 50,000 persons at the last Census, 8049 births and 4697 deaths were registered during the week ended Saturday, June 12th. The annual rate of mortality, which had been 15·4, 13·7, and 13·9 per 1000 in the three preceding weeks, fell in the week under notice to 13·5 per 1000 of their aggregate population, estimated at 18,136,180 persons at the middle of last year. During the first ten weeks of the current quarter the mean annual death-rate in these towns averaged 16·0, against a corresponding rate of 16·3 per 1000 in the metropolis. The annual death-rate last week ranged from 4·4 in Hastings, 6·6 in Eastbourne, 6·8 in Enfield, 7·0 in Hornsey, and 7·6 in Newport (Mon.), to 20·1 in Blackpool, 21·1 in Bury, 23·5 in Cambridge, 24·3 in Middlesbrough, and 29·1 in Gillingham.

The 4697 deaths from all causes were 150 fewer than the number in the previous week, and included 449 which were referred to the principal epidemic diseases, against 439 and 489 in the two preceding weeks. Of these 449 deaths, 215 resulted from measles, 90 from infantile diarrhœal diseases, 75 from whooping-cough, 33 from diphtheria, 29 from scarlet fever, and 7 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases was equal to 1·3, or 0·1 per 1000 less than in the previous week. The deaths attributed to measles, which had been 309, 221, and 239, in the three preceding weeks, fell to 215 last week, and caused the highest annual death-rates of 2·3 in Wigan, 2·4 in Sunderland, 2·5 in Derby, 3·3 in Sheffield, 4·5 in West Bromwich, and 6·2 in Middlesbrough. The deaths of infants (under 2 years) referred to diarrhœa and enteritis, which had been 70, 64, and 75 in the three preceding weeks, further rose to 90 last week, and included 21 in London, 6 each in Liverpool and Manchester, and 4 each in West Ham and Birmingham. The fatal cases of whooping-cough, which had been 137, 90, and 90 in the three preceding weeks, further fell to 75 last week, of which 16 belonged to London and 4 each to Liverpool, Wigan, Manchester, Leeds, and Sheffield. The deaths attributed to diphtheria, which had been 51, 31, and 50 in the three preceding weeks, fell to 33 last week, and included 9 in London, and 2 each in Birkenhead, Liverpool, Bradford, and Sheffield. The deaths referred to scarlet fever, which had been 20, 21, and 22 in the three preceding weeks, further rose to 29 last week, of which 5 were registered in London, 3 each in Bradford and Sheffield, and 2 each in Tottenham, Liverpool, Manchester, and Salford. The fatal cases of enteric fever, which had been 15, 11, and 13 in the three preceding weeks, fell to 7 last week, of which 3 occurred in Manchester.

The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, which had been 2286, 2252, and 2267 at the end of the three preceding weeks, had increased to 2336 on Saturday last; 330 new cases were admitted during the week, against 320, 257, and 327 in the three preceding weeks. These hospitals also contained on Saturday last 1058 cases of diphtheria, 91 of measles, 49 of enteric fever, 12 of whooping-cough, and 1 of small-pox. The 1103 deaths from all causes in London were 48 fewer than the number in the previous week, and corresponded to an annual death-rate of 12·7 per 1000. The deaths referred to diseases of the respiratory system, which had steadily declined from 469 to 181 in the eight preceding weeks, further fell to 165 last week, but were 22 in excess of the number in the corresponding week of last year.

Of the 4697 deaths from all causes in the 96 towns, 279 resulted from different forms of violence, and 401 were the subject of coroners' inquests, while 1394 occurred in public institutions. The causes of 34, or 0·7 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in London and in its 14 suburban districts, in Manchester, Sheffield, Bristol, Bradford, Hull, and in 57 other smaller towns. Of the 34 uncertified causes, 9 were registered in Birmingham, 3 in Liverpool, and 2 each in Gillingham, St. Helens, Preston, South Shields, and Gateshead.

HEALTH OF SCOTCH TOWNS.

In the 16 largest Scotch towns, with an aggregate population estimated at 2,345,500 persons at the middle of this year, 1123 births and 806 deaths were registered during the week ended Saturday, June 12th. The annual rate of mortality in these towns, which had been 16·1, 18·2, and 18·9 per 1000 in the three preceding weeks, fell to 17·9 per 1000 in the week under notice. During the first ten weeks of the current quarter the mean annual death-rate in these towns averaged 18·8, against 16·0 per 1000 in the large English towns. Among the several towns the death-rate last week ranged from 7·1 in Kilmarnock, 10·0 in Motherwell, and 12·4 in Ayr, to 20·9 in Dundee, 22·0 in Leith, and 23·7 in Aberdeen.

The 806 deaths from all causes were 42 fewer than in the previous week, and included 148 which were referred to the principal epidemic diseases, against numbers increasing from 90 to 147 in the three preceding weeks. Of these 148 deaths, 80 resulted from measles, 40 from whooping-cough, 12 each from scarlet fever and infantile diarrhœal diseases, and 4 from diphtheria, but not one from enteric fever or from small-pox. The mean annual death-rate from these diseases was equal to 3·3, against 1·3 per 1000 in the large English towns. The deaths attributed to measles, which had been 36, 72, and 85 in the three preceding weeks, fell to 80 last week, and included 52 in Glasgow, 17 in Aberdeen, and 3 in Edinburgh. The deaths referred to whooping-cough, which had been 40, 43, and 40 in the three preceding weeks, were again 40 last week, of which 23 occurred in Glasgow, 5 in Edinburgh, and 3 in Dundee. The fatal cases of scarlet fever, which had been 6, 5, and 7 in the three preceding weeks, further rose to 12 last week, and comprised 6 in Glasgow, and 3 each in Edinburgh and Aberdeen. The deaths of infants (under 2 years), attributed to diarrhœa and enteritis, which had been 5, 15, and 10 in the three preceding weeks, rose to 12 last week, and included 5 in Glasgow, 3 in Dundee, and 2 in Aberdeen. The 4 fatal cases of diphtheria were 4 below the average in the earlier weeks of the quarter, and were all registered in Glasgow.

The deaths referred to diseases of the respiratory system, which had been 117, 141, and 145 in the three preceding weeks, fell to 126 in the week under notice, but were 31 in excess of the number registered in the corresponding week of last year. The deaths attributed to different forms of violence numbered 25, against 26 and 35 in the two preceding weeks.

HEALTH OF IRISH TOWNS.

In the 27 town districts of Ireland, with an aggregate population estimated at 1,212,380 persons at the middle of this year, 536 births and 357 deaths were registered during the week ended Saturday, June 12th. The annual rate of mortality in these towns, which had been 18·3, 16·4, and 17·0 per 1000 in the three preceding weeks, fell to 15·4 per 1000 in the week under notice. During the first ten weeks of the current quarter the mean annual death-rate in these towns averaged 19·3, against corresponding rates of 16·0 and 18·8 per 1000 in the English and Scotch towns respectively. The annual death-rate last week was equal to 17·0 in Dublin (against 12·7 in London and 19·1 in Glasgow), 13·7 in Belfast, 15·6 in Cork, 21·5 in Londonderry, 19·0 in Limerick, and 11·4 in Waterford, while in the 21 smaller towns the mean rate was 14·0 per 1000.

The 357 deaths from all causes were 39 fewer than the number in the previous week, and included 21 which were referred to the principal epidemic diseases, against 20 and 27 in the two preceding weeks. Of these 21 deaths, 9 resulted from whooping-cough, 7 from measles, 2 each from diphtheria and infantile diarrhœal diseases, and 1 from scarlet fever, but not one from enteric fever or from small-pox. The mean annual death-rate from these diseases was equal to 0·9, against corresponding rates of 1·3 and 3·3 per 1000 in the English and Scotch towns respectively. The deaths attributed to whooping-cough, which had been 5, 3, and 5 in the three preceding weeks, further rose to 9 last week, and included 3 in Londonderry, and 2 each in Dublin and Cork. The deaths referred to measles, which had been 9, 10, and 3 in the three preceding weeks, rose to 7 last week, of which 5 occurred in Belfast. The 2 deaths from diphtheria were registered in Dublin, those from infantile diarrhœa in Belfast and Queenstown, and the fatal case of scarlet fever in Belfast.

The deaths referred to diseases of the respiratory system, which had been 93, 63, and 56 in the three preceding weeks, rose to 64 in the week under notice. Of the 357 deaths from all causes, 107, or 30 per cent., occurred in public institutions, and 3 resulted from different forms of violence. The causes of 8, or 2·2 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest; in the 96 English towns the proportion of uncertified causes did not exceed 0·7 per cent.

A FREE TUBERCULOSIS DISPENSARY AT ST. BARTHOLOMEW'S HOSPITAL.—A dispensary has been established at St. Bartholomew's Hospital, at which residents in the City or non-resident workers suffering from any form of tuberculosis may receive advice and treatment free. The dispensary, which is the outcome of an arrangement between the City Corporation and the hospital, is open between the hours of 12.30 and 2.30 P.M. on Tuesdays and Fridays Special cases receive attention on Thursday evenings.

TYPHUS FEVER, LICE, AND THE WAR: A SUGGESTIVE FACT.

To the Editor of THE LANCET.

SIR,—In the annotation in your issue of June 12th entitled "The Spread of Typhus Fever by Lice," you mention a circular issued by the German Imperial Board of Health which advocates the use of a preparation containing sabadilla vinegar. This at once recalled to my mind a statement contained in a letter which I received in January last from Mr. James Flind, the administrator of the La Guaira and Caracas Railway, Venezuela. He told me that during the year 1913 no less than 258 tons of sabadilla seed were shipped from La Guaira to Germany, the shipment in former years averaging something over 100 tons per annum. He says, further, "Owing to the war, the sabadilla is now being shipped, but in smaller quantities, to the United States, and we have never shipped any of it to England. The uses for this seed are not fully known here, but it is thought that it is used in the curing of hides and as a medicine for horses and animals." In the light of your note it would certainly seem that we have here additional proof, if any were needed, that Germany had carefully prepared for the war which she intended to bring about as soon as it suited her convenience.

The most important active principle of sabadilla is, of course, veratrine, which is used to some extent in veterinary practice as a parasiticide, and also enters into the composition of a preparation sometimes employed for treating pediculosis of the scalp.

It must be remembered that veratrine is a very poisonous substance, and preparations containing it must be used with caution. Doubtless the German Imperial Board of Health pay due attention to this point in their circular.

I am, Sir, yours faithfully,
ANDREW BALFOUR.

Wellcome Bureau of Scientific Research, London, W.,
June 14th, 1915.

THE INCIDENCE OF PLAGUE IN EUROPE.

To the Editor of THE LANCET.

SIR,—In THE LANCET of Nov. 14th, 1914, I put forward some contentions with regard to the incidence of plague in Europe. I attempted to explain why it is that whereas formerly great epidemics were rife, nowadays no such occurrences take place.

First, I endeavoured to establish the fact that the brown rat having replaced the black was to a large extent the reason for the changed condition of affairs. The disappearance of plague was coincident with the introduction of the brown rat; and in the seaport towns where the black rat is still largely prevalent small epidemics do occur.

Secondly, I tried to find an explanation of this, and I concluded that the reason was to be found in the different bionomics of the two species of rat.

Thirdly, I tried to show that whatever danger there was to man from epizootics among brown rats, the danger was much minimised in the summer months. I gave certain figures in support of this, and I concluded that the reason for what I took to be a fact was that the rats, being widely dispersed over the countryside in summer, were, *pari passu* with that dispersal, less exposed to infection, and therefore to epizootics.

Now Dr. R. St. J. Brooks, writing in THE LANCET of Dec. 19th, 1914 (which has just come to my hand in a corner of Malaya, May 4th, 1915), challenges the figures by which I tried to prove that rats were less liable to epizootics in the summer. He says that, as a matter of fact, an average flea-rate per rat of 2·7 produced an epizootic of 11 per cent. in one parish in England (I said that a flea-rate of 1 per rat had done so, having misinterpreted Martin and Rowland's original paper, or not seen the figure that Dr. Brooks gives); and not only does he say that I was wrong in that, but that I had compared my figures for that parish with something that was not strictly comparable—to wit, the incidence of plague among 15,000 rats, which had a flea-rate of 4·5, caught later in a great many parishes.

I do not know why these figures are not comparable. I contend that if a flea-rate of 2·7 (admitting the new figure) causes an epizootic of 11 per cent. among 123 rats in a town, village, or hamlet, then a flea-rate of 4·5 should cause a much greater epizootic than 0·2 per cent. among any 15,000 rats one likes to examine. Of course, it is possible if 15,000 more rats had been examined a heavy infection would have been found among them (this is only admitting that there is an "error of random sampling"); all I am concerned with is the fact that among 15,000 rats which were examined, with an average of 4·5 fleas per rat, there was no heavy infection, and I want to know the reason why.

As a matter of fact, if Dr. Brooks still does not consider these figures comparable I will give him some parish for parish figures.

—	Parish.	Plague.	Flea-rate.
Martin and Rowland (Winter, 1910).	?	11% epizootic.	2·7
Strickland and Merriman (Summer, 1911).	Nacton.	Nil.	6·5
	Tuddenham.	,,	6·0
	Tattingstone.	,,	5·3
	Hollesley.	,,	5·1

The difference in these figures for neighbouring parishes all in the infected area for winter and summer is striking and needs some explanation, and I think I have hit on the right and natural one when I say it is due to the dispersal of the rats over the country-side in summer.

Dr. Brooks finally says my "assumption is erroneous." It is not quite clear from his letter whether he refers only to the last or to all three of my contentions. The reader is rather led to infer that one of my figures having been given wrongly the whole thesis was upset. As a matter of fact, his criticism was directed only against my third contention, and I think I have shown that it was captious and inconsequent. After all, if Dr. Brooks admits the dispersal of the rat population in the summer time, would he not expect a lessened incidence of plague among them? Even if Dr. Brooks will not admit the lessened incidence of plague in summer as compared with winter, will he not make it clear whether, while recognising the lessened incidence of plague nowadays as compared with the past, he disputes my first two contentions: (1) that it has been due to the replacement of the black rat by the brown;

and (2) that the reason for this is found in the difference of bionomics in the two species of rat?

Until Dr. Brooks sets up some thesis more reasonable than that of my three contentions I hold that mine may stand.

I am, Sir, yours faithfully,

C. STRICKLAND,
Travelling Medical Entomologist, Federated Malay States Government.
Malaria Bureau, Kuala Lumpur, F.M.S., May 5th, 1915.

DIAGNOSIS OF TUBERCULOSIS.

To the Editor of THE LANCET.

SIR,—The article by Dr. G. H. Dart on this subject in THE LANCET of June 12th must have been of great interest to all those who are doing tuberculosis work, and who are, in consequence, examining numbers of contacts daily. I think one and all will agree with Dr. Dart with regard to the great difficulty in many cases of making a definite diagnosis, especially so in childhood, at the first examination. I have a special opportunity of watching these difficult and anomalous cases at the Kensal House Open-air School, which is under my medical supervision, and to which this particular class of case is admissible.

It seems to me, from a clinician's standpoint, almost impossible to lay down any hard-and-fast rules with regard to symptoms, physical signs, or special tests (such as Moro's, von Pirquet, &c.), as to which case should be classed as "definite" and which "suspect," as there are never two cases exactly alike; consequently each case must be judged, so to speak, on its own merits. Then, again, in many cases the final diagnosis can only be made after having had the child under observation in an open-air school or some such institution for some considerable time.

It is obvious that no scheme for dealing with tuberculosis can be complete without an open-air school.—I am, Sir, yours faithfully,

R. SEPTIMUS WALKER,
Medical Officer, Paddington Tuberculosis Dispensary.
June 15th, 1915.

PULSUS ALTERNANS.

To the Editor of THE LANCET.

SIR,—Dr. J. Davenport Windle's comments in THE LANCET of June 12th on one of the tracings attached to my paper on pulsus alternans, which appeared in your issue of May 29th, are of very considerable interest, and, as I well know, the subject is one on which he speaks with special authority. Nevertheless, I think I can assure him that the tracing was not produced in the way he suggests. The patient was not the subject of laboured breathing, and in whatever position she was placed a tracing some 12 or 14 inches in length exhibited throughout the perfectly regular alternation which is displayed in the short example. Perhaps it may be well to add that the tracing was taken not through the agency of a tambour, but directly by Dudgeon's sphygmograph. Dr. Windle's second point is of great importance, as it proposes a method of distinguishing between a pulsus alternans which is of serious import and one which is free from anxious significance. But is he not a little severe in challenging my tracing as a true picture of pulsus alternans because of the absence of a feature which, as he himself says, has not hitherto been mentioned as one of the characteristics of this condition? If the tracing conforms to the recognised descriptions it may surely claim the corresponding title, though the new test proposed by Dr. Windle may be a possible method of appraising its exact prognostic significance. The measurements on which he insists must obviously receive the attention of all who are interested in graphic methods, and on this particular issue it would be of interest to have his opinion on my Fig. 1 (*a*) where the downstroke of the weaker beat is definitely shorter than that of the stronger. This tracing would therefore seem to satisfy the new condition which he presents as essential to a true pulsus alternans. But both Fig. 1 (*a*) and Fig. 6 (*a*) are tracings taken from one and the same patient.

May I be allowed a word in recognition of Sir James Goodhart's interesting letter in your issue of June 5th? The question he raises of the relative values of sphygmometric and sphygmographic records does not seem to have engaged the attention it merits. In THE LANCET of Feb. 18th, 1911, I tried to show that the sphygmometer can at the best relate only to level or height of pressure, while for information relative to the duration of pressure and to the fashion of its decline an appeal must be made to the sphygmograph. On the other hand, at least such was my claim, the sphygmograph makes no announcement of the height to which the pressure rises, and therefore the terms "high pressure" and "low pressure," as commonly applied to its readings, are unjustified and misleading. I am, Sir, yours faithfully,

June 14th, 1915. C. O. HAWTHORNE.

THE GRATUITOUS TREATMENT OF DEPENDENTS.

To the Editor of THE LANCET.

SIR,—I was glad to see the letter of "M.D." in THE LANCET last week. At the beginning of the war, when this was proposed, no one realised what the nation was in for, and the suggestion was quite fitting and proper. Now that the matter has grown to such dimensions it is becoming a burden. The whole service should be properly arranged with fitting remuneration. As it is, half my patients now come under this category, and soon some of us on whom an unfair share of this work happens to fall will find themselves unable to continue. Other State work is remunerated, why not this?

I am, Sir, yours faithfully,

June 14th, 1915. SATIS.

⁂ By the same post a letter from a correspondent in Vancouver reaches us saying: "At the commencement of the war the Medical Society of Victoria, British Columbia, decided that wives and children of soldiers on active service should be attended gratuitously, but owing to great abuse of the members' services that resolution has now been rescinded."—ED. L.

LITERARY INTELLIGENCE.—Messrs. Henry Frowde and Hodder and Stoughton announce the publication within the next few weeks of a series of Oxford War Primers of Medicine and Surgery, to be written mainly by medical officers in the naval and military services who have had special experience of the subjects. The series will be issued under the general editorship of Lieutenant-Colonel D'Arcy Power, R.A.M.C.(T.).

DEATH OF AN ABERDEEN MEDICAL MAN.—Dr. J. E. Fowler, a well-known medical practitioner in the Woodside district of Aberdeen, died on June 11th in the seventy-sixth year of his age. The whole of his professional life had been spent in the district where he lived, and he took a keen interest in public affairs. When Woodside was a separate burgh he held the office of Provost.

The War.

THE CASUALTY LIST.

THE names of the following medical officers have appeared in the casualty lists since our last issue:—

Killed: Second Lieutenant A. Clifford Clifford, 3rd Dragoon Guards, was a Guy's man and M.B. Cantab.; Lieutenant-Colonel J. W. Jessop, 4th Battalion Leicestershire Regiment (T.F.), of Horncastle, Lincolnshire, was also a medical man (M.R.C.S., L.R.C.P.).

Died of wounds: Surgeon T. L. G. Stewart, R.N.; Lieutenant D. G. Watson, R.A.M.C.

Wounded: Captain R. M. Dickson, R.A.M.C., Major G. H. L. Hammerton, Yorks Mounted Brigade F.A. (T.F.), Captain H. L. Gregory, attached 7th Middlesex Regiment (T.F.), Lieutenant G. Bailey, 1st East Lancashire F.A. (T.F.), Major T. Holt, attached 6th Lancashire Fusiliers (T.F.), Captain H. Henry, attached 4th East Lancashire Regiment (T.F.), all of the R.A.M.C. (T.F.); Surgeon R. Creasy, Divisional F.A., and Surgeon W. Bradbury, Medical Unit, both of the R.N.; Captain R. Knowles, I.M.S., Lieutenant-Colonel W. R. Pearless, N.Z. Army Medical Corps.

DEATHS AMONG THE SONS OF MEDICAL MEN.

The following must be added to the sons of medical men who have fallen in the war: Second Lieutenant G. F. Blacker, only son of Dr. A. E. Blacker, of Clifton; Lieutenant-Commander R. S. Parsons, R.N., fifth son of Dr. Charles Parsons, of Tunbridge Wells; Second Lieutenant T. A. Heywood, only son of Dr. T. W. Heywood, of Darwen; Major E. L. Baddeley, eldest son of the late Dr. Baddeley, of Whalley; Lieutenant W. A. Leland, eldest son of Dr. Alfred Leland, of Kensington; Lieutenant E. F. Thorburn, youngest and only surviving son of Professor William Thorburn, of Manchester; Second Lieutenant A. J. I. Donald, eldest son of Dr. Archibald Donald, of Manchester.

THE BRITISH CASUALTIES.

Mr. Asquith has now given to the House of Commons statistics regarding the casualties amongst officers and men of the Royal Navy, Royal Marines, and Royal Naval Division to May 31st. The figures include the casualties resulting from the loss of the *Bulwark* and other accidental losses. The figures are as follows:—

	Officers.	Men.
Killed	549	7,696
Wounded	181	2,262
Missing	74	2,785
Total	804	12,743

This makes the total of casualties in the Senior Service of all ranks 13,547.

In the House of Commons on June 9th Mr. Asquith stated that our total casualties in the French and Mediterranean Expeditionary Forces up to the end of May (i.e., for ten months) amounted to 10,955 officers and 247,114 non-commissioned officers and men, killed, wounded, and missing, the figures not including the losses among the naval forces, that is, not including the figures given above. Of the total losses in the army the killed numbered 3327 officers and 47,015 non-commissioned officers and men. In no previous war of which we have accurate statistical records has there been so great a loss of life in a similar period of time, and the figures dealing with the army can be submitted to certain rough comparisons.

Throughout the Crimean campaign the British losses were 2755 killed and 12,094 wounded; and our Allies lost 8250 killed and had 39,868 wounded. In the Franco-German War of 1870–71, during the whole period from July to April, the Germans had 17,570 killed and 96,189 wounded. In the Russo-Turkish War of 1877 the Russians lost 32,780 killed and had 71,268 wounded. In the South African War there were 5256 killed in action and 26,286 wounded. In the absence of authoritative statistics as to the numbers of men engaged, it is impossible to compare the relative losses by wounds and by death in the present campaign with previous experiences. At Waterloo the British killed in action amounted to 4·85 per cent. of the troops engaged; the wounded were 16·25 and the missing 2·19 per cent. In the Crimea our losses were 2·81 per cent. killed and 12·35 per cent. wounded. In the Franco-German War the German troops lost 1·97 per cent. killed and 10·83 per cent. by wounds. In the South African War we lost 1·25 per cent. of the force in battle and 2·46 per cent. by disease.

In an attempt to compare the conditions of the present campaign with those of previous wars, in regard to the amount of injury done by one force to the other, the points that must seem the most noticeable are the immense number of combatants, the great extent of the battle lines, the continuous character of the fighting, and the use by each side of arms of great precision, both small arms and artillery. Never before has there been such a concurrence of factors towards the production of an enormous loss of life and limb, and in these circumstances there is little in past precedent to guide us in making any estimates or deductions. We can, certainly, compare the relative proportions of the killed and wounded (including in the latter category the missing, who may be killed or may be prisoners) in the present war with the proportions that have prevailed in the past, and the figures are of better omen than would be expected. The ratio is as 1 killed to 4·25 wounded and missing, or 23·5 per cent. In the Crimea the ratio of killed to the number wounded and missing was as 1 to 4·4, or 22·7 per cent.; in the Franco-German War of 1870 it was as 1 to 5·70, or 17·53 per cent.; in the Russo-Turkish War it was as 1 to 2·17, or 45·98 per cent.; in South Africa it was as 1 to 5, or 20 per cent. The proportion of killed to wounded has therefore so far been similar to, but slightly in excess of, our experiences in the Crimea and South Africa.

Among officers, the proportion of killed to wounded has been in the present war much higher than in the case of the men—namely, as 1 to 2·3, or 43·61 per cent.; it forms our main anxiety. It is said, we do not know with what degree of truth or how widely it is applicable, that our opponents are not led into battle, but that their officers exhort them from the rear rank, and indeed sometimes have to apply some force to make their men advance. This may be mere gossip, or arguing from the particular to the general, and what has certainly taken place in some areas of fighting in the German ranks may have been assumed to be occurring universally. At any rate, there neither is, nor ever has been, any doubt that the British officer (in the words of the drill book) "will lead his company in the assault"; he takes a greater risk, but he knows his men are with him.

TEMPORARY MEDICAL COMMISSIONS AND COMPENSATION.

A medical correspondent asks us whether any arrangements are made, either by the Government, the insurance companies, or the medical profession, to give compensation to any medical man who may either be killed or suffer the loss of a limb or other organ in the war. The gentleman in question had been passed for life assurance by a leading company, but when they learnt that he had applied for a temporary commission in the R.A.M.C. they declined the risk absolutely. As we have had many similar queries, it seems likely that a general statement will be of widespread service. So far as the medical profession is concerned no provision for the granting of such compensation has been made.

As to insurance offices, it is a purely individual matter between the individual candidate and the individual insurance company. It seems quite likely that while perhaps some arrangement could be arrived at between old policy-holders and their company, insurance offices would for the most part decline to take new proposals from those who contemplate going to the front. In any case there would probably be additional premiums for war risk.

With regard to the Government, we are informed by the military authorities that officers (under the rank of colonel) of the Special Reserve of Officers, the Territorial Forces, and those holding only temporary commissions for the purposes of the present war, all stand on exactly the same footing as officers of the Regular Army with regard to compensation for themselves in case of wounds, disease, injury, or disablement consequent on duty, and pensions and compassionate allowances for their families and dependents in case of death. What these gratuities, pensions, and compassionate allowances are under varying conditions and for different ranks in the service can be learnt from the Royal Warrant for Pay, Appointment, Promotion, and Non-effective Pay in the Army, 1914 (Sections X. and XI., Paras. 639 to 680), to be obtained, price 6*d*., either directly or through any bookseller, from Wyman and Sons, Limited, London and Cardiff; H.M. Stationery Office, Edinburgh; and E. Ponsonby, Limited, Dublin.

WAR SERVICE AND THE BRIGHTON MEDICAL PROFESSION.

The Brighton Division of the British Medical Association has adopted the following scheme for assisting medical men who are rendering medical war service. A copy of the scheme has been sent to all practitioners in the area, who are invited to sign the following declaration and return it to Mr. E. Burchell, the honorary secretary:—

> I am willing, during the conditions of emergency caused by the war, to attend, on the terms and conditions formulated below, the patients of other practitioners in this district who are engaged on military duties. I will not attend on my own behalf any patient of a practitioner for whom I have acted under this agreement within one year from the termination of that practitioner's military duties. I agree to accept half of all fees earned as payment for the services I render, or, in the cases of insured persons, a portion of half the quarterly cheque received from the Insurance Committee, which shall be determined by the number of insured persons attended by me during that quarter. If I wish to withdraw from this undertaking, I will give the Hon. Sec. of the Executive Committee, Brighton Division, B.M.A., not less than 14 days' notice. I am willing to undertake: (1) Private practice; (2) practice under the Insurance Act; (3) Poor-law practice. (4) Although unable to undertake work in any of the kinds of practice enumerated, I agree to be bound by the principles of the scheme. [The signatory deletes those kinds of practice he is not willing to undertake.]

From the signatures to this undertaking a list of all practitioners willing to attend patients of absentees on war service is drawn up, and any practitioner leaving on military service may select by agreement with them any or all of the practitioners on the list to attend his patients, it being understood, of course, that only those willing to attend Insurance Act or Poor-law patients shall be called upon to do so. A circular letter, of which the following is the approved form, is sent to all the patients whose names have been on the books of the doctor for the previous two years and who, there is no reason to suppose, have since become patients of another doctor:—

> Dr. X desires to inform you that, having undertaken military duties, he will be absent from his practice after ...., 191.... By mutual arrangement, the doctors named below have undertaken to attend his patients during his absence. To assist in carrying out this arrangement, you are particularly requested to inform the doctor whose services you require that Dr. X is your usual medical attendant. Those doctors whose names are marked with an asterisk are willing to attend patients under the Insurance Act, and insured persons on Dr. X's list calling in another doctor will remain on that doctor's list until the return of Dr. X.

The patients on receipt of this circular will select from the list appended thereto by their own medical attendant one of the doctors named thereon, with limitations already specified as to the kind of practice. The payment to the substitute doctor in the case of private patients shall be half of all fees earned, the fees being those usually charged by the absent practitioner. In Insurance Act cases one-half of the quarterly cheque from the Insurance Committee shall be retained by the absent doctor, the other half being divided pro rata among those doctors who have attended his insurance patients. The accounts for medical attendance undertaken on behalf of the military medical man shall be sent out by him or by some one appointed by him, and it is urged that he leave power of attorney with some person to act for him during his absence. All sorts of professional services, including consultations, inquests, court fees, and so on, rendered in consequence of such introduction to a military medical man's patients are to be regarded as services rendered on his behalf. Out-of-pocket expenses shall be divided equally between the absent doctor and his substitute, who must keep full records of all attendances and prescriptions given and forward them within 14 days after each quarter day to the absent doctor or his nominee. On returning to practice from military duties the medical man shall make within six months all payments due to those doctors who have acted as his substitutes.

NEW MILITARY HOSPITALS.—The Newcastle City Lunatic Asylum at Gosforth is being transformed into a military hospital. Some 400 wounded men are now being accommodated there, and when the work is complete it will be able to take 1040. Colonel Prescott, R.A.M.C., is in command.—Highbury, Moor Green, the residence of the late Right Hon. Joseph Chamberlain, now a hospital under the control of the 1st Southern General Hospital, received its first batch of 40 wounded men recently. The hospital is to accommodate 145. It is staffed entirely by the Voluntary Aid Detachment from the 30th Worcestershire Division.—The war hospital committee of the Stoke board of guardians has recommended the board to offer to the War Office the female mental wards of their infirmary besides the wards already offered and accepted, with a view to bringing up the hospital accommodation to 500 and meet the problems of staffing and stores. As it was shown that ample accommodation was available elsewhere for the present occupants of the wards the scheme was approved.—The Welsh Metropolitan Military Hospital, with accommodation for 900, was formally opened at the Cardiff Mental Hospital on June 9th. The hospital was handed over rent free, the staff being retained, with military commissions, under the same conditions of pay and service as heretofore. The commandant is Lieutenant-Colonel E. Goodall, the former medical superintendent.—Windlesham Moor, Surrey, providing accommodation for 40 wounded men, has been opened as a military hospital, the owner, Mr. L. B. Peters, having equipped it for that purpose.—A large first-line military hospital is to be erected by the Scottish Branch of the Red Cross Society in Bellahouston Park, Glasgow. It is to contain 700 beds.

WOUNDED ALLIES RELIEF COMMITTEE.—The committee has appointed as Médecin-Chef to the Hôpital Militaire Anglais, Limoges, Mr. C. E. S. Jackson, honorary surgeon of the West Norfolk and Lynn Hospital, and senior assistant medical officer to the Queen Mary's Hospital for Children, Carshalton. The position of Médecin-Chef at the Hôpital Militaire 27a, Dieppe, has been accepted by Captain Owen Paget, of the Australian Army Medical Corps, medical officer of health, Fremantle, Australia. These hospitals, which together treat an average of 300 cases weekly, are entirely supported by the committee and have the approval of the French military authorities.

The doctor at present in charge of the Wounded Allies Relief Committee's typhus hospital at Kragujevac, Serbia, writes as follows: "I think I have succeeded in making the best use of an old artillery stable. It is nothing more or less than a stable which they have given us for our hospital. Everything has been concreted and whitewashed; the sanitary arrangements are very satisfactory; we have water close to the hospital for baths and laundry. In fact, the Wounded Allies Relief Committee's hospital is the cleanest and the smartest hospital at Kragujevac. With the 12 nurses whom you have sent out the nursing staff is more than adequate. The hospital will become a surgical one as soon as possible—that is to say, we are awaiting the surgical instruments to start work. All the staff are quite well and are working with courage and goodwill. The only thing that troubles us is that we have no English papers." The hospital accommodates 100 patients, and Colonel Joseph A'Hearne recently left England to take up the position of medical superintendent. In the meantime the medical work is being admirably performed by two Belgian doctors.

THE BRITISH FARMERS' RED CROSS FUND.—A further sum of £5000 has been sent by the British Farmers' Red Cross Society to the British Red Cross to pay for the British Farmers' Enteric Hospital at Calais. This makes £8000 in all. The Fund has also sent two complete hospitals to Serbia. It is intended to appropriate the next £20,000 collected for the wounded among the British forces at the Dardanelles.

SCHOOLS AS MILITARY HOSPITALS.—From the annual report of the Board of Education it appears that by the month of April the military authorities had taken over for hospital purposes 60 elementary and 17 secondary schools, 8 training colleges, and 2 universities. In addition, there were in occupation as billets, stores, &c., 178 elementary and 18 secondary schools, 14 technical schools, and 2 training colleges. In the great majority of cases the loss of the school premises has not been allowed to stop the work of the school. Local authorities, managers, and teachers by their efforts have succeeded in minimising the results of this interruption.

CORSTORPHINE HOSPITAL BEDS AT ROUEN AND BOULOGNE.—As a result of the appeal for funds in the parish of Corstorphine the sum of £234 12*s.* 6*d.* has been collected, and it has been decided to endow two beds—one at Rouen and another at Boulogne—the surplus funds being reserved for administration by the Edinburgh Committee of the Red Cross Association.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—An ordinary meeting of the Council was held on June 10th, Sir Frederic Eve, senior Vice-President, being in the chair. The secretary reported that the President left England on May 29th to carry out duties assigned to him by the Admiralty, and would probably be absent for about three weeks. A letter was read from Mr. C. A. Ballance stating that he was going to Malta by request of the War Office and asking the Council to sanction his absence from their meetings. Leave of absence was given. A report was read from the Board of Examiners in Anatomy and Physiology for the Fellowship stating that at the recent examination 42 candidates were examined, of whom 14 were approved and 28 rejected. A report was read from the Court of Examiners stating that at the recent examination for the Fellowship 24 candidates were examined, of whom 8 were approved and 16 rejected. The following are the names and medical schools of the successful candidates:—

Shridhar Bheekajee Gadgil, B.A. Bombay, M.R.C.S., L.R.C.P., Bombay University and University College Hospital; Robert Edward Collins, M.B. Edin., M R.C.S., L.R.C.P., Edinburgh University and St. Bartholomew's Hospital; Louis Carnac Rivett, M.R.C.S., L.R.C.P., Cambridge University and Middlesex Hospital; Lalit Mohan Banerji, M.S. Calcutta, M.R.C.S., L.R.C.P., Calcutta Medical College and St. Bartholomew's Hospital; Arthur Oliver Gray, M.R.C.S., L.R.C P., Middlesex and St. Bartholomew's Hospitals; James Renfrew White, M.B., Ch.B. New Zealand, M.R.C.S., L.R.C.P., Otago University and Middlesex Hospital; Charles Jennings Marshall, M.D. Lond., M.R.C.S., L.R.C.P., Charing Cross Hospital; and Benjamin Thomas Edye, M.B., Ch.M. Sydney, Sydney University and St. Bartholomew's Hospital.

Diplomas of Member were also conferred upon the following gentlemen who have now complied with the by-laws:—

George Maudsley Jackson, Bristol University; and Charles Wainwright Fort, Manchester University.

In accordance with a report from the Board of Examiners in Dental Surgery it was resolved to issue Licences in Dental Surgery to the following successful candidates:—

Arthur Bramston Austin, Middlesex and Royal Dental Hospitals; Edward Doane Barrows, D.M.D. Harvard, Charing Cross and Royal Dental Hospitals; John Leycester Dudley Buxton, University College and Royal Dental Hospitals; James Arthur Balfour Carson, Middlesex and Royal Dental Hospitals; Leopold Harold Cross, Guy's Hospital; Wilfrid Arthur Culverwell, Bristol University and Royal Dental Hospital; William Robert Davies, Liverpool University; Ernest Archibald Dawson, Guy's Hospital; John William Edgar, Middlesex and National Dental Hospitals; Julius Gillis, Middlesex and Royal Dental Hospitals; Cyril Bowdler Henry, Westminster and Royal Dental Hospitals; Walter Sebastian Herman, B.A. Cantab., Cambridge University and London Hospital; Francis William Holgreaves, Liverpool University; Arthur Edmund Lowein and Launcelot Machin, Guy's Hospital; Albert Victor Milnes, Liverpool University; Leonard Stanley Pilbeam and Petrus Lafras van Schalkwijk, Guy's Hospital; Herbert Vernon, Manchester University; Willem Jacobus Rousseau Viljoen, Guy's Hospital; William Harold Waldman, Middlesex and Royal Dental Hospitals; Frederick Harry Wallace, Guy's Hospital; and Leslie Williams, Birmingham University.

It was resolved to close the Museum until further notice. The Council proceeded to elect the examiners for the ensuing year, and all the present examiners were re-elected.

A Member who had been guilty of advertising was removed from the roll.

DEATH OF DR. GEORGE MOORE.—Dr. George Moore, who died recently in his eighty-fourth year at Torquay, practised formerly in Hartlepool, where he was honorary physician to the Hartlepool Hospital and medical officer of health, and later in Jersey, where he was medical superintendent of the lunatic asylum. A student at the Middlesex Hospital, he took the M.R.C.S. in 1853, proceeding later to the M.D. of St. Andrews.

WOMEN'S HOSPITAL FOR CHILDREN, HARROW-ROAD.—At the annual court of this hospital, which was held at Kensington Town-hall on June 10th, a special appeal was made for funds to endow an adequate in-patient department. Countess Brassey, Lady Hall, Miss E. Robins, Dr. L. Garrett Anderson, and Dr. Flora Murray urged the need of the hospital which is staffed entirely by women and situated in a crowded district. At present the in-patients' department has only seven cots. Treatment is given to children up to the age of 14 years.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Naval Casualties.

Mr. Asquith has now given to the House of Commons statistics regarding the casualties amongst officers and men of the Royal Navy, Royal Marines, and Royal Naval Division to May 31st. The figures include the casualties resulting from the loss of the *Bulwark* and other accidental losses. The figures are as follows:—

	Officers.	Men.
Killed	549	7,696
Wounded	181	2,262
Missing	74	2,785
Total...	804	12,743

This makes the total of casualties of all ranks 13,547.

Milk and Dairies Acts Postponement Bill.

A Bill has been introduced in the House of Commons by Mr. Hayes Fisher, on behalf of the Government, to postpone the operation of the Milk and Dairies Act, 1914, and the Milk and Dairies (Scotland) Act, 1914. It was read a first time.

HOUSE OF COMMONS.

Thursday, June 10th.

The War and Epidemics.

Mr. Ginnell asked the Under Secretary for Foreign Affairs whether any international, precautionary or preventive measures were being taken, or instructions issued, against the danger of plague, cholera, or other rapidly spreading disease arising from the war; and, if not, whether the most competent medical advice on the subject would be obtained and made public at the earliest possible date.—Lord Robert Cecil replied: Discussions are in progress between French and British experts as to measures to be taken for the prevention of epidemics, and the civil population will receive ample warning and advice should any danger arise.

Medical Consultants to the Navy.

Mr. Joynson-Hicks asked the Secretary to the Admiralty when the contracts with the six medical men who were receiving £5000 a year from the Admiralty expired; and whether, having regard to the fact that equally eminent doctors were serving with the army at the front for the ordinary pay of Royal Army Medical Corps officers, he would determine the Admiralty contracts at the earliest possible moment.—Mr. Macnamara answered: The question is receiving consideration. I hope a statement may be made shortly.

Treatment of Mental Strain amongst Soldiers.

Mr. Rendall asked the Under Secretary for War whether cases, which in civilian life were uncertifiable, were amongst soldiers being treated as incipiently insane by being placed not under general physicians but under medical officers whose practice as regarded experience in nervous disturbance had been limited to their practice in asylums for the insane; if so, whether such uncertifiable patients as had been subjected to lunacy control had no right, while still in the army, which was comparable to the right possessed by civilians of appeal to a magistrate, and what steps he proposed to take to give soldiers rights equal to those possessed by all civilians.—Mr. Tennant said in reply: Uncertifiable cases of nervous disturbance are being treated in the neurological sections of general hospitals and in addition in two institutions which have been taken over from the Board of Control as military hospitals. In the former they are under the care of selected general physicians and neurologists, in the latter under physicians whose previous experience has been largely that obtained in practice in mental institutions. In all such hospitals the patients have exactly the same rights as a soldier undergoing treatment in a purely military hospital, such as the Herbert Hospital at Woolwich which existed as such in times of peace.

Mr. Rendall: May I take it now that the soldiers are placed under the control of lunacy doctors, and while under such control have not the right of appeal which ordinary civilians have to a magistrate?—Mr. Tennant: I do not think that is a fair deduction to make from my answer.

Mr. Rendall: But is not this the arrangement that the doctors under whom soldiers are placed when they break down mentally, although they are lunacy doctors and have at some time been connected with lunacy establishments, have a right to certify, and that the soldiers have been put under these doctors without any power of appeal?—Mr. Tennant: I think that the statement of my honourable friend goes a little beyond the information I have given him. It is a fact that these medical men have had previous lunacy experience, but they do not necessarily exercise and are not necessarily vested with the same powers as those with which they are vested during peace time over civilians. In these military cases, as I have said, the patient has the same right as a soldier undergoing treatment in a purely military hospital.

Mr. Rendall: Are greater powers not now exercised without there being any right of appeal?—Mr. Tennant: No, sir.

Colonel Yate: May we take that as an assurance that soldiers who break down mentally temporarily are not placed in lunatic asylums?—Mr. Tennant: I have already informed the House that strict orders have been given that cases of this kind are not to be treated as incurable until it is absolutely certain that they are incurable. Every chance is given for the man to be cured.

Colonel Yate: In the meantime they are not placed in an asylum?—Mr. Tennant: No, that is right.

Mr. Rendall: Is any mental case certified while under military control?—Mr. Tennant: Mental cases are not certified until it is necessary to discharge them from the service.

Mr. Rendall asked the right honourable gentleman to state the names of the clearing houses to which soldiers of the rank and file when disabled by nerve strain were sent on arrival from the front, and the names of the military hospitals specially adapted for the treatment of uncertifiable cases of mental strain: how many of these border-line cases were at present in each one of these institutions, indicating at the same time for what purpose the institution was used previous to being commandeered; and in how many instances these uncertifiable cases had been put in charge of medical officers now gazetted officers of the Royal Army Medical Corps who, up to the time when the institutions were commandeered, belonged to the asylum service and who still retained that status in addition to their military status.—Mr. Tennant replied: I am obtaining this information.

Mr. Augustine Roche asked the right honourable gentleman whether soldiers invalided from the front, or who had temporarily lost their mental balance, were to be maintained out of Imperial funds.—Mr. Tennant answered: Soldiers who have temporarily lost their mental balance while with the armies in the field, are at present being retained in the army under treatment at the public expense.

Mr. Rendall: Is it a fact that many soldiers have been put in lunatic asylums in this country?—Mr. Tennant: The number is about 17.

Mr. Rendall: Then there have been some?—Mr. Tennant: By mistake.

Mr. O'Donnell: Will the men go on the local rates after they are declared to be incurable?—Mr. Tennant: I think they go on the local rates, but I am not quite sure.

Naval Surgeons in Charge of Hospital Ships.

Commander Bellairs asked the Under Secretary for War whether the naval surgeons in charge of hospital ships having the rank of fleet-surgeon in the Royal Navy had been given the rank of major in the Royal Army Medical Corps; and whether, having regard to the fact that a fleet-surgeon ranked with a lieutenant-colonel, the latter rank could be accorded to them, no question of pay being involved, instead of degrading them one step in rank.—Mr. Tennant wrote in reply: These officers voluntarily offered their services and accepted the rank of major. They have no experience for army requirements beyond that which is to be obtained by medical charge of hospital ships, and are not, therefore, eligible for service in the rank of lieutenant-colonel.

Housing Accommodation in Wrexham.

Mr. Wardle asked the President of the Local Government Board what action the Board had taken, or intended to take, in connexion with the neglect of the Wrexham town council to carry out the recommendations of the Board, based upon an inquiry held in 1913, to build at least 30 houses suitable for the working classes; whether he was aware that in the report of the Wrexham medical officer of health for 1914 it was stated that at that time there was not a single house vacant at a week's rental of 6s. or less; and whether, in view of the scarcity of working-class accommodation in Wrexham, pressure would be brought to bear on the local authority to take steps to meet the admitted need.—Mr. W. Long answered: The Local Government Board has been in communication with the town council of Wrexham in regard to the provision of houses for the working classes, and the council has made application for sanction to a loan for the erection of 30 houses. A local inquiry in regard to the matter is to be held on June 17th.

Monday, June 14th.

Accumulations of Refuse.

Sir J. D. Rees asked the President of the Local Government Board whether he had issued his proposed circular regarding the accumulation of refuse in the neighbourhood of dwellings, and whether it was to be addressed to rural district, as well as to county borough and urban district councils.—Mr. Long replied: The circular referred to was issued last month[1] to urban authorities. I am considering the issue of another circular to all sanitary authorities urging special precautions for the prevention of disease during the summer months.

Notification of Births Act.

Mr. Lough asked the President of the Local Government Board whether his attention had been drawn to the increase of infant mortality both in London and throughout the country; and whether, having regard to the seriousness and urgency of this question in its relation to the problems created by the war, he could see his way to introduce and pass as an uncontentious measure a Bill which, by the more stringent enforcement of the prompt registration of births, the greater safeguarding of the health of mothers, the establishment of public crèches, or other methods, might tend to abate this evil.—Mr. Long answered: I am fully aware of the importance of this matter, and as I intimated to a deputation on Thursday last, I am anxious to introduce without delay a measure making the Notification of Births Act of general application and conferring certain powers on local authorities for safeguarding the health of infants and expectant mothers. I shall be glad if honourable Members will coöperate with me in securing the unopposed passage of the Bill.

Treatment of Nerve Strain amongst Soldiers.

Mr. Rendall asked the Under Secretary for War to state the names of the clearing houses to which soldiers of the rank and file when disabled by nerve strain were sent on arrival from the front, and the names of the military hospitals specially adapted for the treatment of uncertifiable cases of mental strain; how many of these border-line cases were at present in each one of these institutions, indicating at the same time for what purpose the institution was used previous to being commandeered; and in how many instances these uncertifiable cases had been put in charge of medical officers now gazetted officers of the Royal Army Medical Corps who, up to the time when the institutions were commandeered, belonged to the asylum service and still retained that status in addition to their military status.—Mr. Tennant said in reply: The clearing houses are the Royal Victoria Hospital, Netley, and the 4th London (T.F.) General Hospital, Denmark Hill. These cases are sent to various military hospitals throughout the country and special neurological sections have been established in connexion with the Territorial Force general hospitals so as to bring the patients under the observation of the eminent neurologists at these centres. It is not possible with any degree of accuracy to give the numbers of what my honourable friend calls "border-line cases." The Red Cross Military Hospital, Maghull, and the Springfield War Hospital were taken over as military hospitals through the Board of Control and the superintendents of these institutions were appointed to the charge of the military hospitals when they were taken over. For the time they are purely military medical officers.

Mr. Rendall asked the Under Secretary of State for War whether the new military hospital shortly to be opened at Napsbury had been known for years as a county lunatic asylum; whether its lunacy staff of medical officers were to be retained to take charge of nerve-shattered soldiers without any appeal or judicial investigation; and whether he would consider the possibility, as an alternative, of treating transiently acute cases of nerve-shock in the same way as delirious cases were treated on medical lines in ordinary hospitals, and so save both the injured soldiers and their families from the opprobrium associated with having been treated in a lunatic asylum.—Mr. Tennant replied: The answer to the first two parts of the question is in the affirmative; but I am unaware what appeal or judicial investigation is contemplated by my honourable friend. The cases of nerve-shock to which the word "transient" may be applicable will be sent to military hospitals. I can assure my honourable friend that neither the desire nor the intention is lacking in my military medical advisers to save the soldiers and their families from the opprobrium associated with having been treated in a lunatic asylum.

Battalion Medical Officers.

Sir Philip Magnus asked the Under Secretary for War whether there was any shortage of battalion medical officers in the army; if so, what steps were being taken to remedy such shortage; and whether the Army Medical Department was conferring with the official representatives of the medical profession in this country with a view to the better organisation of the medical profession for war purposes.—Mr. Tennant answered: There is not at present any shortage of battalion medical officers, but more are still required in order that the needs of the new Army and the Territorial Force may be fully supplied. Considerable numbers are being engaged every week, and the Director-General of the Army Medical Service is receiving every support from the official representatives of the civil medical profession with whom, not only on this but also on other matters affecting the health and well-being of the troops, he is in constant and cordial relations.

The King George Hospital.

Sir Philip Magnus asked the Under Secretary for War whether he could state how many medical officers were at present employed at the King George Hospital, Stamford-street; how many of these were of military age; what was the proportion of such officers to the number of patients, and how that proportion compared with the proportion of medical officers to patients in the general medical hospitals; whether men above the age of 40 were eligible for appointments at the King George Hospital; and whether the staff of younger men might be reduced if they were assisted by medical men over 40 years of age working part time.—Mr. Tennant said in reply: The medical officers of this hospital were appointed by the Red Cross Society and I understand that there are 25 resident and 24 are of military age, though I cannot say how many of these are, in fact, eligible for any service. There is one medical officer to 66 beds, which is a somewhat more favourable proportion than in other hospitals. An arrangement of part-time service would not be convenient, I believe, but I sympathise with the object the honourable gentleman has in view, and inquiries will be made to see whether any of the junior medical officers who are eligible could be released for general medical service with the army.

Precautions against Asphyxiating Gases.

Sir Arthur Markham asked the Under Secretary for War: 1. Whether, seeing that Dr. Haldane was requested by the Government to report on the poisonous gases used by the Germans, he was aware that Dr. Haldane at once instructed Mr. S. F. Winmill, B.A., B.Sc., chief chemist of the Doncaster Coalowners Scientific Research Committee, to make tests of the best forms of respirators for the use of the troops, and that Dr. Haldane stated that the form of respirator proposed to be issued by the War Office was of no value whatever; whether, notwithstanding this, Lord Kitchener made an appeal to the women of the country to make these respirators; whether many men at Hill 60 lost their lives at Hill 60 when using this respirator; and whether the Director-General of Medical Services was consulted and approved this pattern of respirator. 2. Whether, seeing that Mr. Winmill had presented a report to the Doncaster Coalowners Scientific Research Committee that men could, if they took certain precautions, evade poison gases without even using respirators, he would say whether Dr. Haldane and Mr. Winmill had been asked by the War Office to make any report on the question; whether, if no such report had been asked for, he would at once ask Dr. Haldane to make a brief report stating the precautions which would prevent loss of life even though no respirator was used or available; and would he see that this report was at once sent to General Sir John French. 3. Whether he was aware that Dr. Haldane was recognised in all countries as one of the greatest living physiologists, his books being the recognised standard authority; whether he was aware that Dr. Haldane had for years past given his services to the Home Office to assist in obtaining a reliable breathing apparatus for use in mines; and whether he was aware that Dr. Haldane has made innumerable tests of all types of breathing apparatus.—Mr. Tennant answered: The eminence of Dr. Haldane as an authority is of course well known, and he has advised the War Office on the matter in question and continues to advise. The type of respirator used at the outset was that approved by the Admiralty, and it was adopted with the approval of the Director-General of the Army Medical Service until a more suitable type could be devised for the special circumstances. I have on previous occasions explained the circumstances in which an appeal was made to the public. I have no knowledge of the report made by Mr. Winmill, but I may inform my honourable friend that Dr. Haldane has already indicated certain protective measures that may be taken by troops, if they happen to be without one of the authorised respirators, and the necessary instructions have been given by the military authorities in France. The means of protection now in use are reported on most favourably by the authorities in France. Recourse has been had in studying these problems to all the best brains in the country.

TUESDAY, JUNE 15TH.

Notification of Births Act.

Mr. Snowden asked the President of the Local Government Board whether he was aware that the latest return of the Registrar of Births showed that the birth-rate in London was now from 400 to 500 per week below the average of the last five years, that children had been dying in London during the last 13 weeks at the rate of 200 per week above the rate for the corresponding weeks of last year, that the increased mortality among children was general throughout the country, that this increase was attributed to causes connected with the war, that the problem was now so serious that if the present rate be continued for 42 weeks all the infants would have succumbed; in view of the state of things would he at once meet the defects in the present law by a small Bill to amend the Notification of Births Act, empowering local authorities to make such arrangements as might be sanctioned by the Local Government Board for securing the health of mothers and infants; and would he at the same time respond to the many appeals which have been made to his department to make the Notification of Births Act universal, especially in view of the fact that 1 child in 10 born died within 48 hours of birth.

---

[1] THE LANCET, June 5th, p. 1190.

Sir George Toulmin asked the right honourable gentleman whether he was prepared to introduce legislation for the amendment and strengthening of the Notification of Births Act.—Mr. Long (replying to both honourable Members) said: The births registered in London during the second quarter of this year averaged 79 per week fewer than the corresponding weekly number in the past five years, and during the 13 weeks ending June 5th there has been a weekly excess in the deaths of children under 5 years of age averaging 169. This excess has been mainly due to an exceptional prevalence of measles and whooping-cough with their usual sequelæ. The suggestion in the question that, if the present rates be continued for 42 weeks, all the infants will have succumbed, is, I am happy to say, devoid of foundation, as is also the statement that 1 child in 10 dies within 48 hours of birth. As regards the legislation suggested in the two questions, I would refer to the answer which I gave yesterday, in which I stated that I was anxious to introduce without delay a measure making the Notification of Births Act of general application, and conferring certain powers on local authorities for safeguarding the health of infants and expectant mothers.

Wednesday, June 16th.

Royal Army Medical Corps.

Colonel Yate asked the Under Secretary for War whether, considering that between July 31st, 1914, and March 31st, 1915, only 14 captains in the Royal Army Medical Corps were promoted majors, and during the same period some 97 majors were promoted lieutenant-colonels, he would now take steps to have a corresponding number of captains promoted to the rank of major.—Mr. Tennant replied: The majors were promoted to the rank of lieutenant-colonel to fill appointments for officers of that rank. The promotion of captains will be considered as and when majors are required. There is no fixed establishment of the latter rank, and under ordinary circumstances promotion to it goes by time qualification.

Appointments.

Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to The Lancet *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

Ahearn, M. J., has been appointed Medical Officer of the Lowpark Dispensary District by the Swinford Board of Guardians.

Davies, Howard, M.R.C.S., L.S.A., has been appointed Temporary Medical Officer of Health and Superintendent of the Isolation Hospital, Pontypridd.

Ibotson, Edward C. B., M.D., B.S. Lond., L.S.A., has been appointed Certifying Surgeon under the Factory Act for the Civil Parish of Talyllyn and part of Machynlleth Rural District.

McMillan, A. Lewis, M.D., C.M. Glasg., has been appointed Consultant Eye Specialist to the Glasgow Corporation Hospitals.

Ogilvie, W. M., M.B., C.M. Aberd., has been appointed Medical Superintendent of the Ipswich Borough Mental Hospital.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

When the application of a Belgian medical man would be considered the advertisers are requested to communicate with the Editor.

Aberdeen, University of.—Examiners.

Bath, Winsley Sanatorium for Consumption.—Assistant Resident Medical Officer. Salary £250 per annum, with board, residence, and laundry.

Bexley, Kent, London County Asylum.—Locum Tenens Medical Officer. Salary 6 guineas a week, with quarters, board, and washing.

Birkenhead Borough Hospital.—House Surgeon. Salary £300 per annum, with board and laundry.

Birmingham General Dispensary.—Resident Medical Officer, unmarried. Salary £250 per annum, with apartments, attendance, &c.

Birmingham and Midland Eye Hospital.—Junior House Surgeon. Salary £100 per annum, with residence, board, &c.

Blackpool County Borough.—Clinical Tuberculosis Officer.

Bolingbroke Hospital, Wandsworth Common, S.W.—House Surgeon. Salary £100 per annum, with board-residence.

Bolton Infirmary and Dispensary.—Senior House Surgeon. Salary £230 per annum, with apartments, board, and attendance.

Bristol Royal Infirmary.—Assistant to Ear, Throat, and Nose Department.

Brook War Hospital, Shooters Hill, Woolwich.—Resident Assistant Surgeons and Physicians. Salary £1 a day, with residence, board, and lodging.

Bury Infirmary.—Senior and Junior House Surgeons. Salary £175 and £150 per annum respectively, with board, residence, and washing.

Cardiff, Welsh Metropolitan War Hospital, Whitchurch, near Cardiff.—Pathologist and Bacteriologist. Salary £1 per day, with board, apartments, and washing.

Carlisle Non-Provident Dispensary.—Resident Medical Officer. Salary £200 per annum, with apartments (not board).

Chelsea Infirmary, Cale-street, S.W.—Assistant Medical Officer. Salary £300 per annum, with rations, apartments, and washing.

Cirencester, Glos., 1st South Midland Mounted Brigade Field Ambulance.—Two Medical Officers to complete 2nd Line (Territorial).

Evelina Hospital for Sick Children, Southwark, S.E.—Clinical Assistants in Out-patient Departments.

Folkestone, Royal Victoria Hospital.—House Surgeon. Salary as agreed, with board, residence, and laundry.

General Lying-in Hospital, York-road, . S.E.—Resident Medical Officer for three months.

Guildford, Royal Surrey County Hospital.—House Surgeon. Salary £150 per annum, with board, residence, and laundry.

Hospital for Consumption and Diseases of the Chest, Brompton.—House Physician for six months. Salary 30 guineas. Also Assistant Resident Medical Officer. Salary £100 per annum, with board and residence.

Inverness, Northern Infirmary.—House Surgeon. Salary £150 per annum, with board, &c.

Leamington Spa, Warneford, Leamington, and South Warwickshire General Hospital.—Second Resident Medical Officer. Salary £200 per annum, with board, residence, and laundry.

Leeds Public Dispensary.—Female Resident Medical Officer Salary £130 per annum, with board, residence, and laundry.

Macclesfield General Hospital.—House Surgeon. Salary £150 per annum, with board and residence.

Manchester County Asylum, Prestwich.—Locum Tenens. Salary 6 guineas per week.

Manchester Northern Hospital for Women and Children. Park-place, Cheetham Hill-road.—House Surgeon. Salary £120 per annum, with apartments and board.

Margate, Royal Sea-Bathing Hospital for Surgical Tuberculosis.—Resident Surgeon. Salary at rate of £150 per annum, with board, residence, and laundry.

National Hospital for Diseases of the Heart, Westmoreland-street, W.—Resident Medical Officer for six months. Salary at rate of £80 per annum, with board, residence, and washing.

New Zealand War Contingent Association, 25, Victoria-street, London, S.W.—Two Visiting Surgeons.

Norwich Incorporation.—District Medical Officer. Salary at rate of £100 per annum.

Norwich, 3rd Line Depôt, 2nd East Anglian Field Ambulance.—Medical Officers. Pay and allowance as in Regular Army.

Nottingham General Hospital.—Senior House Physician and Assistant House Physician. Salary at rate of £300 and £250 per annum respectively, with board, residence, and laundry.

Oldham County Borough.—Assistant Schools Medical Officer. Salary £325 per annum.

Plymouth, South Devon and East Cornwall Hospital.—House Surgeon and House Physician. Salary as arranged, with board, residence, and washing.

Poplar and Stepney Sick Asylum, Devon-road, Bow, E.—Temporary Assistant Medical Officer. Salary 7 guineas per week, with board and residence.

Portsmouth Workhouse Infirmary, Workhouse, and Children's Home —Female Second Assistant Medical Officer. Salary £150 per annum, with apartments, rations, &c.

Queen Charlotte's Lying-in Hospital, Marylebone-road, N.W.—District Resident Medical Officer for four months. Salary at rate of £60 per annum, with board, residence, and washing.

Rhondda Urban District Council.—Temporary Assistant Medical Officer of Health and School Medical Officer. Salary £350 per annum.

Royal Eye Hospital, St. George'e-circus, Southwark, S.E.—House Surgeon. Salary £75 per annum, with board, apartments, and washing.

St. Mary's Hospital for Women and Children, Plaistow, E.—Assistant Resident Medical Officer. Salary at rate of £90 per annum, with board, residence, and laundry.

Salford County Borough.—Medical Officer for Maternity and Child Welfare work. Salary £300 per annum.

Salisbury General Infirmary.—House Surgeon and Assistant House Surgeon, unmarried. Salary £150 and £100 per annum respectively, with apartments, board, lodging, and washing.

Sheffield Royal Infirmary.—House Surgeon and Assistant House Physician. Salary £100 per annum, with board and residence.

Sheffield, Wharncliffe War Hospital, Middlewood-road.—Resident Medical Officers.

South London Hospital for Women, 88-90, Newington-causeway, S.E.—Female Anæsthetist.

Southampton, Parish Infirmary, Shirley Warren.—Resident Assistant Medical Officer. Salary £250 per annum, with apartments, rations, washing, and attendance.

Stockport Infirmary.—Senior House Surgeon. Salary £200 per annum, with board, washing, and residence.

Sunderland Royal Infirmary.—Resident Medical Officer. Salary £150 per annum, with board, residence, and laundry.

Swansea General and Eye Hospital.—House Physician. Salary £200 per annum, with board, apartments, and washing.

TUNBRIDGE WELLS GENERAL HOSPITAL.—House Surgeon, unmarried. Salary £250 per annum, with board, residence, &c.

VENTNOR, ROYAL NATIONAL HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Isle of Wight.—Assistant Resident Medical Officer.

WALSALL AND DISTRICT HOSPITAL.—Assistant House Surgeon and Anæsthetist. Salary £150 per annum, with board, residence, and laundry.

WARRINGTON INFIRMARY AND DISPENSARY.—Senior and Junior House Surgeons. Salary £180 and £120 per annum respectively, with board, apartments, and laundry.

WEST BROMWICH AND DISTRICT HOSPITAL.—House Surgeon and Assistant House Surgeon, unmarried. Salary £150 and £120 per annum respectively, with residence, board, and laundry.

WEST HAM AND EASTERN GENERAL HOSPITAL.—Resident Medical Officer. Salary £160 per annum. Also House Physicians and House Surgeons. Salary £120 and £100 per annum respectively, with board, residence, and washing.

WEST HAM UNION.—Third Assistant Medical Officer and Fourth Female Assistant Resident Medical Officer at Infirmary, Whipps-Cross-road, Leytonstone, N.E. Salary £200 and £180 per annum respectively. Also Female Resident Assistant Medical Officer at Workhouse, Union-road, Leytonstone, N.E. Salary £180 per annum. Each with usual residential allowances.

WIGAN, ROYAL ALBERT EDWARD INFIRMARY AND DISPENSARY.—Junior House Surgeon. Salary £150 per annum, with board, apartments, and washing.

THE Chief Inspector of Factories, Home Office, London, S.W., gives notice of vacancies for Certifying Surgeons under the Factory and Workshop Acts at Buckhaven, in the county of Fife; at Kirkham, in the county of Lancaster; at Market Bosworth, in the county of Leicester; and at Rothes, in the county of Elgin.

Births, Marriages, and Deaths.

BIRTHS.

BOURNE.—On June 13th, at Nottingham-place, W., the wife of Lieutenant A. W. Bourne, F.R.C.S., of a daughter.

LINTON.—On June 14th, at Tunbridge Wells, to the wife of Captain F. C. Linton, R.A.M.C. (T.), a son and a daughter.

MILLIGAN.—On June 4th, at Hessle, Yorks, to Dr. and Mrs. H. P. Milligan, a son.

ROPER.—On June 8th, at Biscovey House, Par, Cornwall, to Dr. and Mrs. Charles Roper, a son.

WEBB.—On June 9th, at "Moreton," Park Drive, Hampstead, to Lieutenant G. Harvey D. Webb, R.A.M.C. (T.F.), and Mrs. Harvey Webb, a daughter.

MARRIAGES.

EVANS—RUTHERFORD.—On June 10th, at Dunkeld Cathedral, Albert Edward Evans, M.B., to Jessie Dorothy, second daughter of the Rev. T. R. Rutherford, M.A., Minister of Dunkeld.

PARROTT—MEADE.—On June 15th, at St. Michael's Church, Greinton, Harold Winnock Parrott, M.B, B S., son of A. G. Parrott, M.R.C.S., L.R.C.P., of Shanghai, to Ella Mary, daughter of Mr. and Mrs. Frank Meade, of Greinton, Somerset.

ROOK—CALWAY.—On June 12th, at St. George's Church, Wilton, Taunton, Henry Colwell Rook, Lieutenant, R.A.M.C. (S.R.), to Alice Marguerite, elder daughter of Mr. and Mrs. F. Calway, of Henley Lodge, Taunton.

SCHOFIELD—OVER.—On June 11th, at Crowthorne, Berks, Harry Schofield, R.A.M.C., to Nellie, fourth daughter of Mr. and Mrs. H. Over, Wellesley House, Crowthorne, Berks.

DEATHS.

HOLLIS.—On June 4th, at Tower House, Freshwater, Isle of Wight, Alfred Hollis, M.D., aged 69 years.

MOORE.—On June 10th, at Torquay, George Moore, M.D., J.P., in his 84th year.

TREWMAN.—On June 13th, suddenly, George Turner Trewman, Lieutenant-Colonel, R.A.M.C., aged 59 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

MONSTERS AND SCHRECKLICHKEIT.

So the "wild girl of Naini Tal," who received notice in these pages some months ago, is now pronounced on good authority to be an ordinary imbecile. All men are inclined to be mythopoetic in such matters, for there lingers in the human breast a tendency to discover prodigies, inherited from savage ancestors. Monsters of all kinds, including "wild" children, were indeed better known to a more primitive generation than to the present; and at one time the production of monsters was an industry having for its double object pecuniary gain and the satisfaction of superstition. An Italian work was published as lately as the closing years of the nineteenth century in order to show the manner in which monstrosities can be produced and grown. Once alive and kicking, your monstrosity can be exhibited to the public for cash. An old authority on prodigious births is Lycosthenes. In his "Prodigiorum et Ostentorum Chronicon," published at Basle in 1557, are some remarkable recitals. He describes, for instance, a cadet of a noble Polish house who was "terrible to behold," for he was born with flaming and shining eyes. His mouth and nostrils were similar to those of an ox. He had also long horns and a back hairy as a dog's, and cat's eyes, which were situated far below his chest—we are not told exactly where. These eyes looked "hideously and frightfully." Furthermore, this Pole "had the heads of dogs upon both elbows and at the whirlbones of each knee." His feet resembled those of the swan, and he possessed "a tail which was crooked backwards about half an ell long," so that sitting down was impossible. Born at Cracow, this noble Polish cadet remained perfectly silent until within an hour of his death, when he uttered the one word "Watch," which was held to refer to one or other of the many revolutions of the time (1543).

Even the most rational of medical men concerned themselves with descriptions of abnormalities. Ambroise Paré describes a small monster, of the Molline family at Antwerp, "wholly like a dog, save that it had a shorter neck and the head of a bird." Also a young Savoyard, who had a long piece of flesh, like a French hood, hanging down from the nape of his neck almost to his heels, while two other pieces, like the collar of a shirt, were wrapped round his neck. He had also white boots of flesh on his legs, doubled down like the boots of brigands in old-world melodrama. The Duke of Savoy caused him to be brought to court, "which performed, one would hardly imagine the various censures the courtiers gave of the creature."

Now Paré, a Frenchman, and Lycosthenes (Conrad Wolffhart), who was a professor of Basle and a native of Alsace, were both inheritors of noble traditions of culture. If in matters touching monstrosity these enlightened men were credulous, how much more so must have been the inhabitants of remote and half-civilised regions. Northern Germany, for instance, is known to have long possessed an intensive tradition of monstrosity and of the terrible, dating from the mythologic epoch. A more grandiosely dreadful, a more Apocalyptic picture than that of the entire annihilation of the world by the Powers of Darkness and Fire, which is the climax of the "Prose Edda," has perhaps never been painted. But the monsters of Germanic mythology and of mediæval medical men are only terrible in vague outline. It was left to a mild Saxon lunacy expert of modern times, Dr. Heinrich Hoffmann, to introduce into the petty mythology of the nursery a pair of degenerates in the persons of the ever-memorable "Struwwelpeter," the self-neglecting little monster of weak intellect, and *der böse Friderich, der wahrer Wüterich*, who dismembered flies and killed birds and cats. The ten episodes in the classic "Struwwelpeter," a chap-book for the nursery, which was published in 1845 and had reached its fortieth thousand before 1860, are mostly of the bloodthirsty kind.

SANITARY CONVENIENCES IN SHOPS.

THE Committee appointed by the Government to consider the question of further enlistment in the distributing trades have represented to the Local Government Board that a difficulty arises in the case of the smaller shops in releasing men of military age for service in the army and replacing them by women by reason of the provisions of the Public Health Acts requiring separate sanitary accommodation for each sex. The Government at the moment are appealing to shopkeepers to set free all their male staff who are medically fit for service, and of age for enlistment. It is found, however, in many cases that separate sanitary accommodation for the two sexes is not available on the premises and such accommodation is required by the Acts. It will be hard on the employer if, having already lost many male assistants, he is called upon to make structural alterations in his premises to meet conditions which are only intended to be temporary, while the need will especially arise in small shops where female labour has not yet been employed. The requirements of the Acts cannot, of course, be dispensed with, and the Board suggest that the difficulty may be met by some temporary arrangement, such as the use, free of charge, of a convenience in a neighbouring house, or of a public convenience near by. We believe that in the case of factories and workshops, where the same problem has arisen, arrangements of this kind have been adopted, with the consent or concurrence of the Inspector of Factories, and have proved satisfactory; and no other economical course is possible. We trust that the sanitary officers, to whom circulars have been issued, will ascertain whether temporary arrangements of the kind indicated can be made, and will generally facilitate the action of any shopkeeper who is willing to allow his male assistants to join the army.

FATAL EXPECTANCY.

To the Editor of THE LANCET.

SIR,—Recently in a conversation with a medical officer in charge of a department especially devoted to tuberculosis he expressed the opinion that he would exclude a diagnosis of pulmonary tuberculosis until a third or even a fourth examination of the sputum revealed each time the presence of T.B., the local symptoms being indefinite and suspicious only. Not, be it observed, that he would exclude the diagnosis only after a third or fourth examination proved negative. Such a view if generally held must surely be fatal to the campaign against consumption. It would be interesting to know if this view is prevalent. Sceptics are not the class from whom progress may be expected in any sphere of life, whereas enthusiasts, though they are apt to fly too high, do help the world to progress. To wait until the symptoms are definite and unmistakable and the complaint has got a firm hold is not good either for the individual or for preventing it spreading.

I am, Sir, yours faithfully,

City-road, E.C., June 10th, 1915. J. J. UDALE.

LIME-JUICE.

WITH the advent of the hot weather there is likely to be a demand for cooling drinks, especially for lemonade and lime-juice. In the South African War lime-juice was provided for the troops in jars and barrels, and quantities were held in reserve at various places, and there is little doubt that far greater amounts of this beverage will be consumed this summer. For the wounded officers and for certain wounded men there is a supply of iced champagne, but an army cannot be kept refreshed on such a costly beverage, even if available. In 1903 Sir Wodehouse Richardson said: "Powdered lime-juice can now be obtained, 2 or 3 ounces of which make several gallons of a very palatable beverage. It is thus far more portable than lime-juice in barrels or bottles. The medical authorities would have to be consulted before this powder could be adopted." We do not know to what medical authorities this refers, unless to the army medical authorities, but the merits of a powder as against a liquid call for careful consideration on the grounds of preservation of the essential properties, keeping qualities in hot weather, freedom from admixture, intentional or accidental, flavour, and so forth.

SCOPOLI.

To the Editor of THE LANCET.

SIR,—With your permission I would supplement your note on Scopolamine on p. 1272 of to-day's issue of THE LANCET by some references to Signor Giovanni Antonio Scopoli, the great naturalist of Cavalese, in the Tyrol, where he was born on June 15th, 1725, 190 years ago. From M. L. Hahn we learn that Scopoli studied the humanities at Trieste and medicine at Innsbruck, where he took his doctorate in 1745. At Innsbruck he developed a strong love for natural history, botany first attracting his attention. As there was no teacher of natural history in the University he was practically self-taught, and formed the basis of a natural classification which much more nearly approaches to Ray's natural one than that of Linnæus. He collected a large number of the plants indigenous to the mountains of Tyrol, and formed the design of publishing a flora of his native country. But the project was defeated by his being called to Styria and afterwards to Vienna, hence he came to Idria, where he obtained a medical appointment. But his love of natural science drew him away from the routine work of medicine, and with renewed energy he applied himself to the study of botany. His mental activity, however, was so great that he embraced in his curriculum entomology, mineralogy, and chemistry. Whilst in practice in Idria he found time to write his famous "Flora Carniolica," which was published in 8vo at Vienna, 1760, in which book it may be noted that he followed the Linnean classification. His entomology, "Entomologia Carniolica," published in Vienna, 1765, illustrated by some 40 odd engravings, was not a financial success, though it greatly increased his reputation. His interest in the subject of minerals was excited by seeing the extensive use made of mercury in the Styrian mines, and in 1771 his "Mineralogische Vorlesungen" was published at Vienna. Of medical writers he was one of the first to call attention to diseases incidental to industrial occupations. The removal of Jacquin to Vienna from Chemnitz left a vacancy for a mineralogist for the great Hungarian mines which Scopoli was called to fill, and in the year of his appointment, 1777, he published his "Fundamenta Chemiæ" at Prague. Soon afterwards he was appointed professor of natural history at Padua, which chair he occupied until his death in 1788.

I am, Sir, yours faithfully,

Dublin, June 12th, 1915. GEORGE FOY.

THE LATE LORD ROBERTS ON THE TREATING OF SOLDIERS.

A FEW days ago a soldier arrested for drunkenness in London gave as his explanation that he had returned from the front wounded and that a lady had treated him to a bottle of whisky. Now, this is not the way to welcome returned soldiers, and we would redirect attention to the letter from the late Lord Roberts published in THE LANCET of Nov. 10th, 1900, in which he said: "Will you kindly allow me, through the medium of your paper, to make an appeal to my countrymen and women upon a subject I have much at heart and which has been occupying my thoughts for some time past. All classes in the United Kingdom have shown such a keen interest in the army serving in South Africa, and have been so munificent in their efforts to supply every need of that army, that I feel sure they must be eagerly looking forward to its return and to giving our brave soldiers and sailors the hearty welcome they so well deserve when they get back to their native land. It is about the character of this welcome and the effect it may have on the reputations of the troops whom I have been so proud to command that I am anxious and that I venture to express an opinion. My sincere hope is that the welcome may not take the form of 'treating' the men to stimulants in public-houses or in the streets, and thus lead them into excesses which must tend to degrade those whom the nation delights to honour, and to lower the 'soldier of the Queen' in the eyes of the world—that world which has watched with undisguised admiration the grand work they have performed for their sovereign and their country. From the very kindness of their hearts, their innate politeness, and their gratitude for the welcome accorded them, it will be difficult for the men to refuse what is offered to them by their too generous friends. I therefore beg earnestly that the British public will refrain from tempting my gallant comrades, but will rather aid them to uphold the splendid reputation they have won for the Imperial army."

Lord Roberts's warning seems to be urgently needed at the present juncture.

THE NATIONAL CLEAN MILK SOCIETY.

THE aims of this society are to raise the hygienic standard of milk and milk products, and to educate the public in regard to the importance of securing a clean and wholesome milk-supply. Plans are now being decided upon by the council for a clean milk and infants' welfare station to be established in one of the poorest quarters of London, where clean milk can be sold to the poor, and where mothers can be educated in the care of their babies on lines similar to those that have proved useful in New York. The movement will have medical approval, and we should be glad to see it develop, rapidly and successfully, all over the country. Money, of course, is needed to carry on this important hygienic work, and the council, which is a strong one, containing several well-known leaders of our profession, appeal to the public to support the movement by becoming members of the society. Communications should be addressed to the secretary, 2, Soho-square, London, W.

THE OPEN-AIR TREATMENT OF THE WOUNDED.

UNDER the title of "The Open-air Treatment of the Wounded," Dr. A. E. Shipley, F.R.S., Master of Christ's College, Cambridge, has written a description of the First Eastern General Hospital, Cambridge, for the *Country Life* Library. The book is an eloquent plea for fresh air in the treatment of disease, and the remarkable statement is made that this form of treatment reduces the expense per bed from £200 to £16. In a footnote Lord Knutsford says that Dr. Shipley's estimate of £200 per bed for an ordinary hospital is too low, £300 to £400 being nearer the truth in a London hospital. Professor W. J. R. Simpson, C.M.G., in a chapter on open-air treatment, gives the number of patients who have passed through the Cambridge Hospital as 6600, with a death-rate of only 4·6 per

1000. Of 60 cases of pneumonia that have been treated in the hospital, 95 per cent. have recovered. The book, which is well illustrated, is published by the proprietors of *Country Life*, 20, Tavistock-street, Covent Garden, W.C., price 1s. net.

T. L. Cashel.—The various eponymous terms can all be found by reference to one of the medical dictionaries, of which there are several. The best of these, we regret to state, are of American origin.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East.

TUESDAY AND THURSDAY.—5 P.M., Croonian Lectures:—Surgeon-General Sir David Bruce, C.B: Trypanosomes causing Disease in Man and Domestic Animals in Central Africa. (Lectures II. and III.)

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Dr. Simson: Diseases of Women. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. D. Armour: Operations. Dr. Pritchard: Bacterial Therapy Department. Mr. B. Harman and Mr. Gibb: Diseases of the Eye.

TUESDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations. Dr. Simson: Diseases of Women. Mr. Gibb: Diseases of the Eye.

THURSDAY.—9 A.M., Dr. Bernstein: Bacterial Therapy Department. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. D. Armour: Operations. Mr. B. Harman: Diseases of the Eye.

FRIDAY.—10 A.M., Dr. Simson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Eye Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY.—Clinics:—10.30 A.M., Surgical Out-patients (Mr. E. Gillespie). 2.30 P.M., Medical Out-patients (Dr. T. R. Whipham); Gynæcological Out-patients (Dr. Banister). 3 P.M., Medical In-patients (Dr. R. M. Leslie).

TUESDAY.—2.30 P.M., Surgical Operations (Mr. Carson). Clinics:—Medical Out patients (Dr. A. G. Auld); Surgical Out patients (Mr. Howell Evans); Nose, Throat, and Ear Out-patients (Mr. H. D. Gillies). Radiography (Dr. Metcalfe). 3.30 P.M., Medical In-patients (Dr. A. J. Whiting).

WEDNESDAY.—Clinics:—2.30 P.M., Throat Operations (Mr. Gillies). Children Out-patients (Dr. T. R. Whipham); Eye Out-patients (Mr. R. P. Brooks); Skin Out-patients. 5.30 P.M., Eye Operations (Mr. R. P. Brooks).

THURSDAY.—2 30 P.M., Gynæcological Operations (Dr. A. E. Giles). Clinics:—Medical Out-patients (Dr. A. J. Whiting); Surgical Out-patients (Mr. Carson); Radiography (Dr. Metcalfe). 3 P.M., Medical In-patients (Dr. R. M. Leslie). 4.30 P.M., Clinical Demonstration:—Dr. A. E. Giles: Illustrative Gynœcological Operations.

FRIDAY.—2.30 P.M., Surgical Operations (Mr. Howell Evans). Clinics:—Medical Out-patients (Dr. A. G. Auld); Surgical Out-patients (Mr. E. Gillespie); Eye Out-patients (Mr. R. P. Brooks).

THE THROAT HOSPITAL, Golden-square, W.

MONDAY.—5.15 P.M., Special Demonstration of Selected Cases.

THURSDAY.—5.15 P.M. Clinical Lecture.

For further particulars of the above Lectures, &c., see Advertisement Pages.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

The Croonian Lectures

ON

TRYPANOSOMES

CAUSING DISEASE IN MAN AND DOMESTIC ANIMALS IN CENTRAL AFRICA.

Delivered before the Royal College of Physicians of London on June 17th, 22nd, 24th, and 29th, 1915,

By Sir DAVID BRUCE, C.B., F.R.S.,
M.B. Edin., F.R.C.P. Lond.,
SURGEON-GENERAL, A.M.S.

LECTURE I.

Delivered on June 17th.

Mr. President and Gentlemen,—I beg to thank you for the honour you have conferred in electing me Croonian lecturer for the present year. I am afraid the subject I have chosen will be found to be of little or no practical interest to the Fellows of this College, since it deals with a form of tropical disease which is seldom seen in England, and then, as a rule, only in hospitals devoted to the treatment of exotic diseases. The investigations into these diseases were also made from the standpoint of causation and prevention rather than treatment, a circumstance which must further lessen their interest to physicians engaged almost exclusively in the treatment of disease. But this is the subject which for some years has almost exclusively engaged my attention, and on account of the pressure of work caused by the war it would have been difficult or impossible to gather materials on any other subject. Further, I intend to confine myself in these lectures to a consideration of the trypanosomes causing disease in man and domestic animals in Central and Southern Africa, since it is only in Zululand, Uganda, and Nyasaland that I have had the opportunity of studying these parasites in the field and under natural conditions. The conditions, however, which obtain on the East and West Coasts of Africa between 20° N. and 30° S. latitude are much the same as those which are found in the central parts, and it is probable that the same trypanosome species are found throughout. So that in describing the species found in our own colonies it may be assumed that all the important pathological species found in Central Africa are being dealt with, although in other places they may be known by other names.

The central region—the tropical or equatorial—corresponds with the distribution of the tsetse flies, and the trypanosomes causing disease in this region are carried from sick to healthy animals by various species of this genus of flies. In the north of Africa, outside the range of the tsetse flies, two trypanosome diseases are found, one of the horse (dourine) and another of camels (surra), the former conveyed from sick to healthy horses by contagion, the latter almost certainly by large biting flies, the so-called horse flies, or tabanidæ. Now, in order to understand the wide distribution of these hæmatozoa, reference may be made to Fig. 1, a map of the world on which their distribution is shown.

Geographical Distribution.

It will be seen from the accompanying map that these blood parasites are found in most parts of the world, from South America through Africa, Southern Europe and Persia to India, Burma, China, and the Philippines. (Fig. 1.) In Africa is shown a broad equatorial band representing the trypanosome diseases carried by the tsetse flies. In it are represented, for example, the distribution of *Trypanosoma gambiense*, the cause of the ordinary or Congo sleeping sickness, and the distribution of *Trypanosoma brucei*, the cause of nagana in animals, and the Rhodesian and Nyasaland form of sleeping sickness or trypanosome disease in man. Further north out of the tsetse-fly region we have *Trypanosoma equiperdum*, the cause of dourine, which the map shows to be widely distributed in Europe also. *Trypanosoma evansi* or surra, which spreads out of Africa along the camel caravan routes into India and China, is also shown.

In this introduction it is unnecessary for me to give an early account of the history of these parasites, since this has often been done and can be found in most text-books; suffice it to say that the first trypanosomes were discovered some 70 years ago in the blood of fish and frogs. These were of interest to zoologists, but having no obvious bearing on the causation of disease did not attract the attention of medical men. Thirty years afterwards, in 1877, Surgeon Timothy Lewis, of the Army Medical Department, discovered in Bombay the trypanosome of the common rat, which was afterwards named after him—*Trypanosoma lewisi*. Three years later, in 1880, Dr. Evans, Chief of the Veterinary Staff in Madras, discovered what were supposed for a long time to be similar flagellates in the blood of horses suffering from surra. It is from these two discoveries that we must date the beginning of the study of trypanosome diseases.

Classification of the African Trypanosomes.

After these few introductory remarks, and in order to further clear the ground, allow me before proceeding to describe any of the individual species of African trypanosomes to briefly introduce them and to show into what groups or classification they can be thrown. In classifying them I have striven for simplicity, as it seems better for practical purposes to divide them into a few well-defined groups and species rather than to try with our present incomplete knowledge to subdivide them more minutely.

The three characters mainly relied upon in this classification of trypanosomes are, in the first place, their morphology; secondly, their pathogenic action on animals; and, thirdly, their mode of development in the tsetse flies.

At one time it was hoped that cultivation on artificial media might be used as an aid to classification, but up to the present this hope has been unfulfilled. Other methods, such as cross-inoculation experiments and serum diagnosis, I do not consider of much use in making a simple, workable, practicable classification such as will be found of use for diagnosis in the field. If we admit them into our methods the multiplication of species must proceed to an unmanageable degree.

1. *Morphology*.

To begin with the morphology, and this is of great importance in classification. The trypanosomes are first examined in a fresh living condition to ascertain their general appearance and kind of movement. There is a good deal of difference in the range of movement in different species. Whereas many vibrate about one spot, and show little power of wider movement, others are capable of hurling themselves from one point to another with great power and rapidity. But, of course, it is after the trypanosomes have been fixed and stained that their characteristics can be made out best. For example, the length and breadth of a fixed and stained trypanosome may be very useful in identifying it, and in addition to the length and breadth, a description of the contents of the cell, the nucleus, micronucleus, undulating membrane, and flagellum, may all help in the differentiation of species.

2. *Susceptibility of Animals.*

The second means at our disposal for the classification or differentiation of trypanosomes—namely, their pathogenic effect on various experimental animals—must be used with caution. For example, it is well known that their passage through a series of animals of the same species usually exalts their virulence towards that animal. For instance, the nagana parasite, after passage through white rats for many generations, kills the rats in as short a time as two days; whereas the naturally wild strain of nagana only kills the same animals on an average in 20 or 30 days. On the other hand, another species of trypanosome in its natural wild state kills monkeys in a few days. But if it is first passed through a goat, and the attempt is made to infect a monkey with the goat's blood, the experiment always fails. Passage through the goat has lowered the virulence of the parasite towards the monkey. But if a trypanosome is caught in its wild state, and straightway put through a series of experimental animals, the result is, in my opinion, of some use in differentiating species. For example, *Trypanosoma brucei* will be found to be much more virulent and kill off more quickly the various laboratory animals than *Trypanosoma gambiense*. Some trypanosomes are deadly to horses and cattle and harmless to other animals, such as dogs, monkeys, and rabbits, while others show a marked preference for some particular species of animal, such as the domestic pig.

3. *The Development in the Invertebrate Host.*

The third character of use in classification is the mode of development in the tsetse fly or invertebrate host. As already mentioned, all the pathogenic trypanosomes of man and his domestic animals found in Africa, with the exception of the two northern species, pass through a specific cycle of development in the tsetse flies, the mode of development in the tsetse flies is different for different species of trypanosomes, and this may be made use of in classification, and in truth is one of the best means at our disposal. It is not known whether the North African species are capable of developing in tsetse flies. It is possible that on account of disuse they have lost the faculty, if they ever had it. It would certainly be an interesting experiment to try to pass them through the "fly."

CLASSIFICATION INTO THREE GROUPS.

With these few preliminary remarks, let me now introduce the chief Central African pathogenic trypanosomes. They may be divided into three groups, and these are set out on the following scheme:—

Group A. *Trypanosoma Brucei Group.*
1. Trypanosoma brucei.
2. Trypanosoma gambiense.
3. Trypanosoma evansi.
4. Trypanosoma equiperdum.

Group B. *Trypanosoma Pecorum Group.*
1. Trypanosoma pecorum.
2. Trypanosoma simiæ.

Group C. *Trypanosoma Vivax Group.*
1. Trypanosoma vivax.
2. Trypanosoma capræ.
3. Trypanosoma uniforme.

These names probably represent most of the principal pathogenic trypanosomes discovered up

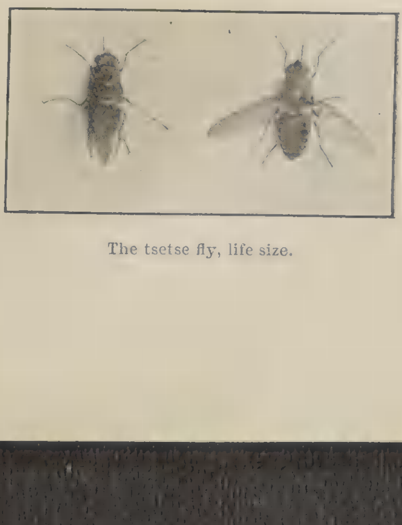
FIG. 9.



The tsetse fly, life size.

to the present time in Central Africa. For the sake of completeness I have placed the Northern species, *Trypanosoma evansi* and *Trypanosoma equiperdum*, in the first group, as they seem by morphology and their action on animals to belong there. Each group is distinguishable or separable by well-defined characters.

Group A. The Trypanosoma brucei group.—The species forming this group (Figs. 2 and 3) are all more or less polymorphic, varying in size and shape from short and stumpy forms without free flagella to long and slender forms with free flagella. The cytoplasm contains numerous dark-staining granules. The micronucleus or kinetonucleus is small, and is situated as a rule some distance from the posterior extremity. The undulating membrane is well developed and thrown into bold folds.

In regard to their action on animals, the members of this group may be said generally to affect many different species of animals—as, for example, man, horses, cattle, dogs, and most of the smaller experimental animals. The two Central African members of the group, *Trypanosoma brucei* and *Trypanosoma gambiense*, develop in the tsetse flies in the same way. At first the development takes place in the intestine; afterwards the parasites pass into the salivary glands, by way probably of the proboscis, and there complete their development into infective forms. This is the only group in which the salivary glands are invaded. This group can be separated from the other groups by shape alone.

Group B. The Trypanosoma pecorum group.—The trypanosomes are small and monomorphic. The cytoplasm is non-granular. The micronucleus is prominent, subterminal, and often seems to project beyond the margin. The undulating membrane is fairly well developed. (Figs. 4 and 5.)

The cycle of development in the tsetse fly in Group B begins in the intestinal tract; afterwards the flagellates pass forward into the proboscis of the fly, and finally reach the salivary duct or hypopharynx, where they complete their development and become infective. The difference between Group A and Group B is that in the latter the salivary glands are never invaded. There are only two species at present included in this group—*Trypanosoma pecorum* and *Trypanosoma simiæ*. The former gives rise to the most important trypanosome disease of cattle in Africa, while the latter is remarkable for the rapidity with which it kills the domestic pig.

Group C. The Trypanosoma vivax group.—The species making up this group (Figs. 6, 7, 8) are monomorphic, and remarkable for the extreme rapidity of their movements. The posterior extremity is enlarged. The cytoplasm is clear and hyaline. The micronucleus is large and terminal, and the undulating membrane is little developed and simple. This species only affects horses, cattle, goats, and sheep. Monkeys, dogs, rabbits, guinea-pigs, and rats are refractory.

The cycle of development in Group C differs from that in Groups A and B in that it takes place at first only in the labial cavity of the proboscis, and later in the salivary duct or hypopharynx. (Fig. 10.) No part of the cycle takes place in the intestinal tract or in the salivary glands.

These three groups are well marked, and it is fairly easy by microscopic examination alone to name what group a trypanosome belongs to, when seen in the blood of the vertebrate host or even in the tsetse fly.

DESCRIPTION OF THE TSETSE FLIES.

General characters.—The insects (Fig. 9) are dull-coloured, ordinary-looking flies about half an inch in length. The strong proboscis stands out horizontally in front. The wings are long and closed over each other, like the blades of a pair of scissors, when the fly is at rest. The dorsal aspect of the abdomen is marked by five more or less distinct transverse bands.

FIG. 10, A.

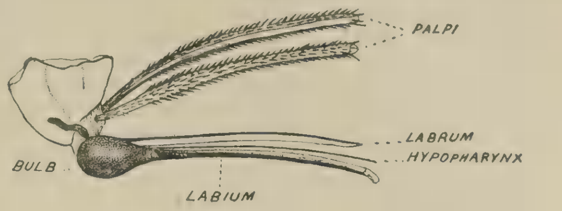


FIG. 10, B.

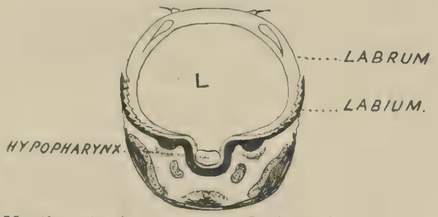


Mouth parts of tsetse fly. L, Indicates labial cavity.

It is important to understand the structure of the proboscis, as this plays an important part in the development of Groups B and C. In Fig. 10 a side view and a transverse section of the mouth parts are given. In the side view the mouth parts—the labrum, the labium, and the hypopharynx or terminal duct of the salivary glands—are separated. This is done by slipping the point of a fine needle between them at the base and running it towards the tip. This separates the labrum from the labium, and, as a rule, the hypopharynx springs up from the hollow of the labium and appears between the two parts as an extremely delicate transparent tube.

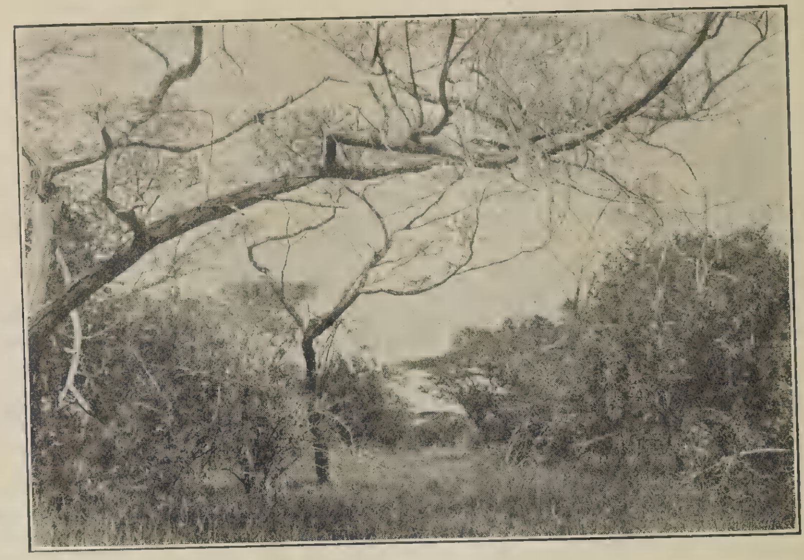
In the transverse section the parts are seen in position, the labrum and labium joined together form a tube through which the blood is drawn in the act of sucking, and known as the labial cavity; and the delicate terminal duct of the salivary glands or hypopharynx lying in the hollow of the labium, and opening near the tip of the proboscis. The salivary glands are long convoluted organs lying chiefly in the abdominal segment of the fly.

When I arrived in Zululand in 1894 there was only one known species of tsetse fly—*Glossina morsitans*. At the present time some 14 or more different species have been named. These are divided into four groups by Austen: The *Glossina palpalis* group; the *Glossina morsitans* group; the *Glossina fusca* group; and the *Glossina brevipalpis* group. For our purpose it will be sufficient to describe the principal species from the first two groups, *Glossina morsitans*, the carrier of *Trypanosoma brucei*, and *Glossina palpalis*, the carrier of *Trypanosoma gambiense*. But I may mention here that probably all the tsetse flies are capable of acting as carriers of all the pathogenic trypanosomes, at least in laboratory experiments. What makes one species of fly the especial carrier of a particular trypanosome is probably bound up in the natural history, the habits, and distribution of the fly.

Habitat.—This is the species made familiar by writings of travellers like Livingstone and hunters like Gordon Cumming. Until a few years ago it was the only species of which the habits had been studied, and when the word tsetse was used it was this species which was meant. Its habitat is the dry, thorny scrub which covers large areas of tropical Africa. (Fig. 11.) It is not found along the banks of lakes or rivers, and, in fact, seems to have a distaste for water. It requires shade, however, and is never found on open plains where it would be exposed to the tropical sun. In the "fly country" there are thickets, undergrowth, and trees which supply the requisite shade.

Habits.—These flies begin to bite soon after sunrise if the day is fine, but usually disappear during the hottest hours, coming out again towards evening when it becomes cooler. About sunset they are often particularly active. Moving objects such as a motor cycle seem to attract them greatly, and the cyclist is often surrounded by a cloud of them attacking him like an angry swarm of bees. Under these circumstances there is often a great disparity in the numbers of the sexes, the males predominating. This is probably due to the males attaching themselves to a moving object in order to mate with the females, which are attracted by the same movement, and come out of their cover to feed. Tsetse flies are very sensitive to weather conditions. If it rains or blows they usually remain hidden. They diminish in numbers during the dry season, and are most numerous towards the end of the rains.

FIG. 11.



Habitat of *Glossina morsitans*.

Food.—In regard to the food of *Glossina morsitans*, in one experiment 500 flies were caught in the sleeping sickness area of Nyasaland, and examined as to the contents of their intestines. It was found that 288 (or 57·6 per cent.) contained mammalian blood in a recognisable state. Measurements of these were made and the small type of blood cell was found to predominate, such as occur in the hartebeeste, waterbuck, and other antelope. In only three cases were nucleated red blood corpuscles found. From this experiment it appears, at least in that district, that the principal food of *Glossina morsitans* is the blood of antelope. Tsetse flies never suck the juices of fruits or vegetables, as is usual in the case of other biting flies such as mosquitoes.

The question is sometimes asked as to how often tsetse flies feed under natural conditions. From experiments with flies in the laboratory it was found that blood is recognisable in stained specimens for two and even three days after a feed, but not beyond the third day. This means, roughly, that half the 500 flies examined had fed within at most three days of their capture; it results that flies feed under natural conditions once in five or six days.

It is rather an interesting point as to whether these flies could maintain an existence on the smaller mammals and birds if the big game disappeared. They are quite ready to feed on the smaller animals, but most of these, such as monkeys, shrews, the mongoose, and rats, are usually too quick and snap up the fly before it has had time to feed. Another curious fact seems to be that when rinderpest sweeps through a country the tsetse flies disappear with the game and only return when the game has again multiplied to a fair extent. The curious point is that by no means all the game is killed off by the rinderpest; there is usually some species left which one would think would suffice to keep numbers of flies in food. It was thought at one time that this mortality among the flies might be due to some poisonous quality in rinderpest blood, but when flies were fed on rinderpest animals nothing untoward happened.

Act of feeding.—In regard to the act of feeding, this is done as a rule very rapidly, the fly fully distending itself in from half a minute to a minute after it has punctured the skin.

Reproduction.—Lastly, we come to the most important function of the tsetse flies, that of reproduction. The genus *glossina* is distinguished from most of the other diptera in being pupiparous. The female produces a single whitish or yellowish-coloured larva about once in ten days. This is retained in the oviduct until it is fully grown. As soon as the larva is born it creeps at once into the soil or into a crack in the earth, or among leaves and débris, and within a few hours has changed into a hard black puparium. As to how long the pupa remains quiescent depends mainly on the temperature. At a temperature of 85° F. the fly will emerge in 23 days, at 70° in 35 days, and at 65° in about 60 days. These larvæ are deposited all over the "fly" country, but there are certain positions and conditions which are favoured. The female usually chooses a spot with plenty of shade. A favourite site for her to take up her abode is on the under-surface of a tree which has fallen, and which remains at places some inches above the ground. Another condition is that the breeding place is near a native path or a game path. This may be to enable the mother to procure her food easily, or it may be some instinct in favour of the offspring which enables the newly emerged fly to obtain a feed within 24 hours of birth.

Glossina Palpalis.

This is also a widely distributed species. It ranges on the west coast from the Senegal river —16° N. latitude—to Angola. It extends eastwards into the Bahr el Ghazal. The eastern boundary of the species follows the valley of the Nile, the eastern shores of Lake Victoria and Lake Tanganyika. From the south end of the latter lake the boundary follows the frontier between the Congo Free State and Rhodesia in a south-westerly direction to Angola.

Habitat.—This species differs from *Glossina morsitans* in being a lover of water. It frequents the edges of lakes and rivers where there is clear water and plenty of shade; this shade consists of thick jungle with high trees and dense undergrowth, which grows to within a few feet or yards of the water's edge. This tsetse fly is never found on open beaches backed by grass plains, even although there may be some low scrub near the water. It is not found in reed beds or papyrus swamps, and as most of the Uganda river valleys are choked with reeds it follows that the tsetse fly does not ascend these rivers. In short, it is never found away from water, except in cases where it has followed man or animals for a mile or so for the purpose of feeding. In this way it is brought much more in contact with man than *Glossina morsitans*, which is a dweller in desert places, the haunt of wild animals. *Glossina palpalis* is a frequenter of watering places, on lakes and rivers, or water-holes in the bush, where the natives come for water, and where as a rule, on account of the density of the human population, there is little game.

Habits.—*Glossina palpalis* has the same habit of biting by daylight as *Glossina morsitans*. It is not seen until the sun is up. If it is a fine morning they may be active as early as seven or half-past seven. On dark shady spots on the lake shore they do not become troublesome until about ten o'clock when the sun is well up. In cloudy or windy weather few flies are abroad. They have a rapid flight and suddenly and silently flop on to the skin, causing so little sensation that the sharp stab of the proboscis is often the first thing felt. Sometimes they insert the proboscis so painlessly that attention is not drawn to the spot. As a rule little or no irritation follows the bite, no itching or swelling or reddening of the skin. But if there have been many bites about the same place there is often a good deal of swelling, induration, redness, and irritation which last for several days, and as is natural some individuals are much more affected than others.

Feeding.—As in *Glossina morsitans* the time taken by the fly in filling itself with blood is short. Stuhlmann weighed the flies before and after feeding and found that the males took in one and a half times their own weight in blood, and the females sometimes as much as two and a half times.

Food.—Under ordinary circumstances in populous districts it may be assumed that man supplies most of the food of this fly, and it is considered by some that it thrives better on human blood than on any other. In captivity, however, it feeds readily on any warm-blooded animal, especially on birds, and if hungry may even be induced to feed on cold-blooded animals, such as the lizard or frog. But in the absence of man it may be remarked that as this species is a dweller on the banks of rivers and lakes, it comes much more in contact with large birds—cormorants and other water-fowl—and reptiles—crocodiles and monitors—than does *Glossina morsitans*. In Uganda before the natives were removed from the lake shore and islands doubtless they formed the chief supply of blood for the fly. On the other hand, after the natives had been removed inland or in places where there was no native population the fly had to adapt its diet to the available supply. One experiment made by us in Uganda in such a place showed that only 17 per cent. of the flies had fed on mammalian blood and 83 per cent. on avian or reptilian, and as far as could be made out twice as many of the flies had fed on reptiles as on birds. In such places the large lizard or monitor seems to be a favourite dish with this species.

Reproduction.—I need not go fully into the reproduction of *Glossina palpalis* as the process is the same as in *Glossina morsitans*. One point may be mentioned, however, and that is that in Uganda the former has a marked predilection for certain breeding grounds; these are sandy beaches along the lake shore backed by a belt of vegetation. The breeding grounds on Damba Island, for example, where some thousands of pupæ were collected every month for the laboratory, are formed of coarse sand and pebbles. It is 4 or 5 feet above the level of the lake, and the bush comes to within a few yards of the water's edge. The pupæ are found as a rule an inch or two below the surface of the sand at or near the edge of the belt of vegetation. For a long time we failed to find any wild pupæ, although days were spent in turning over soil and decaying vegetable matter in those places where the fly most abounds. At last their breeding haunts were discovered by Captain A. D. Fraser, R.A.M.C., to be in patches of sand at the edge of the lake. After this secret was discovered there was no lack. Our natives found them in large numbers. One day they brought up as many as 7000, and as I had promised a cent for each pupa brought up to the laboratory I had to pay out nearly £5 for them. These wild pupæ proved to be much healthier than those obtained from flies in captivity. The flies bred from pupæ born in the laboratory rarely showed any marked vitality; on the other hand, the flies hatched out from the wild pupæ found on the lake shore were fairly strong and vigorous, and lived in captivity for a couple of months or more. In conducting experiments with flies it is very necessary to work with laboratory bred ones, as the wild flies may be naturally infected with several species of trypanosomes. Numerous experiments went to show that there is no hereditary transmission of trypanosomes in tsetse flies, and there is no reason to believe that flies become infected by contact with infected flies or from fouled cages. Any trypanosomes found in laboratory bred flies may therefore be considered to be derived from the infected animal they were fed upon.

It will be seen from the foregoing that the two principal groups of tsetse flies—the *Glossina morsitans* group and the *Glossina palpalis* group—differ from each other in well-marked characters, the former living in wild, unpopulated districts and trusting to the wild game for their food, the latter along rivers and lakes which are usually thickly populated and trusting to man for a food supply, or in his absence living on the large reptiles, birds, and antelopes which frequent these places.

LENGTH OF LIFE OF TSETSE FLIES.

One word more in regard to the duration of life of tsetse flies. This is an important question, but one difficult to answer. The importance comes in when we have to consider how long a place may remain dangerous from the presence of infected flies. I remember at a meeting of the Royal Society when the question came up that the late Lord Avebury said he did not see any reason why a tsetse fly should not live for years. He had himself known an ant to live in captivity for some 15 years. Carpenter tried to solve the question by marking large numbers in a given spot and finding out how long the marked flies could be recaptured. One male was caught 199 days after it had been marked. Kleine states that he kept a fly in captivity for 227 days. If we put the life of the fly, then, at anything up to a year we may not be far out.

I have now given a sketch of the principal pathogenic trypanosomes in Central Africa, and also of their carriers, the tsetse flies. In my next lecture I shall proceed to describe more in detail the individual species of trypanosomes, beginning with that one which causes nagana.

THE USE OF MAGNESIUM SULPHATE IN THE TREATMENT OF TETANUS:

WITH AN ACCOUNT OF A SIMPLE APPARATUS FOR PHARYNGEAL INSUFFLATION.

BY S. J. MELTZER,
ROCKEFELLER INSTITUTE, NEW YORK.

TETANUS, a frequent complication of the wounded in the present war, is a frightful disease. Horrible spasms torture fully conscious victims. Furthermore, it is the spasms which, at least in most cases, cause the fatal issue, by profoundly affecting the functions of respiration and circulation. Accordingly, a treatment which may offer nothing more than relief from these spasms ought to be of considerable importance.

The various experiences accumulated in the last nine years with the use of magnesium sulphate in sporadic cases of tetanus have established beyond a doubt that the spasms of tetanus can be relieved by the use of this remedy to a much greater extent than by any other method of treatment. Furthermore, in many cases of tetanus magnesium sulphate proved to be directly a life-saving remedy. Similar results were obtained with the use of Epsom salts in the extensive experience in the present war. However, by a study of the present numerous brief communications on this subject I became convinced that there is great necessity for a better understanding of the principles underlying this method of treatment, the various methods of administration and their indications, the possible danger due to the use of the magnesium salts, and the means for combating this danger. On the basis of an extensive experimental experience and a study of the clinical literature I formulated definite opinions regarding these various points, which I shall state here as briefly as possible, having in mind exclusively the practical side of our subject.

There are four ways for the administration of magnesium sulphate, each of which has a special action and consequently a special indication. They are: (1) Subcutaneous injection; (2) intramuscular injection, combined with inhalation of ether; (3) intravenous injection; and (4) intraspinal injection. Except for the intravenous injection, the magnesium salt ($MgSO_4 + 7\,H_2O$) shall be given in a 25 per cent. (molecular) solution. In sterilising the solution it must be kept in mind that if evaporation be allowed and not refilled with sterile water, the solution will be much more concentrated and the patient will therefore receive more of the salt. The injections should be made aseptically, or at least antiseptically.

1. *Subcutaneous injections.*—The dose should not be more than 2 c.c. and not less than 1·2 c.c. of the solution (25 per cent.) per kilogramme of body weight, to be injected four times in 24 hours. No massage. Light etherisation or a morphinisation should precede the injection of magnesium.

2. *Intramuscular injection and inhalation of ether.*—It is based upon the finding by Auer and myself that a moderate inhalation of ether increased considerably the efficiency of magnesium salts. Chloroform does not exert such an effect. The patient should be fairly well etherised, and 2 c.c. of a solution of magnesium sulphate (25 per cent.) per kilogramme of body weight be injected into the muscles of the thigh. At the end of the injection the thigh should be massaged and the ether anæsthesia continued lightly for about 20 minutes longer.

3. *Intravenous injections.*—The concentration of the solution should be about 3 per cent. (isotonic), and not more than 5 c.c. per minute should be permitted to run into the vein.

4. *Intraspinal injection.*—The dose to be injected, at the usual place of the lumbar region, should be 1 c.c. (of a 25 per cent. solution) for every 10 kilogrammes of body weight.

Subcutaneous injections exert their effects slowly. They cannot relieve immediately severe or dangerous spasms, but they exert undoubtedly a beneficent effect by cumulative action. Under their influence the spasms gradually become milder and less frequent, and the patient may eventually recover. Subcutaneous injections should be begun as soon as initial symptoms set in (local tetanus, slight trismus, &c.) and be continued throughout the disease. (In very young infants the dose should not exceed 0·8 c.c. per kilogramme of body weight.)

Intramuscular injections plus ether may relieve greatly even severe spasms in less than half an hour, but the beneficial effect is liable to pass off completely after two or three hours. On account of the local reaction which they produce the injections should not be repeated too frequently, and the method ought not to be used as a routine treatment. However, on account of the simplicity of the procedure it may be resorted to in severe spasms when for some reason other methods which are capable of exercising a rapid effect are not practicable.

Intravenous injections are capable of relieving dangerous effects of the spasms (tetanus of the diaphragm, constriction of the larynx) more promptly than any other method of application. But the beneficial effect may completely disappear in less than 30 minutes. Besides, by the use of this method the circulation may become affected also—by the direct action upon the myocardium. The use of this method of injection should therefore be reserved for emergency cases only, when quick action is urgently desired. Pulse and respiration should be guarded during the infusion of the solution; when the pulse shows softness or intermittence, or the respirations show shallowness, the infusion should be at once discontinued. Fortunately the ill-effects, if not permitted to continue too long, disappear quite soon after the infusion is discontinued.

Intraspinal injections may begin to show a definite relief from the spasms in less than half an hour after the injection, and after one hour the relaxation may be complete. The extent as well as the duration of the relief afforded to the patient is greater when the magnesium solution is given by the intraspinal method than by any other method of administration; the relief may last between 12 and 30 hours.

There is a fundamental difference in the mode of action between the intraspinal method and the other three methods of injection. The first acts by local application of the magnesium salts to the hyper-irritable parts of the central nervous system, requires only a small quantity of the solution, and the effect lasts a fairly long time. The other three methods of injection act through the circulation, require much larger doses, and the effect is either moderate and slow in its appearance or is of short duration. There is still another significant difference. The ill-effects upon the respiration caused by injections through the circulation are accessible to a fairly rapid correction by injections of calcium chloride and physostigmine (which will be discussed presently), while these injections have apparently no such beneficial neutralising effects when the respiratory paralysis has been brought about by an intraspinal injection of the magnesium solution.

As stated before, practically the only danger which may arise from an injection of an overdose of magnesium sulphate consists in a paralysis of the respiration. The paralysis is temporary, and when brought about by the administration through the circulation is readily reversible. In many instances an injection of 1·5 milligramme of physostigmine improves the respiration without interfering with the relaxation of the patient. A more reliable reversing effect is obtainable by an injection of calcium chloride. It may be given intramuscularly—30 or 40 c.c. of a 2 per cent. solution. By this method, which has the advantage of simplicity of procedure, the resuscitating action may not be as rapid as desirable; furthermore, it may at times bring back also the spasms, which is surely an undesirable result. The calcium chloride may be administered intravenously in a very dilute solution (0·2 $CaCl_2$ + 0·6 $NaCl$ to 1000 of H_2O) injected slowly. As soon as an efficient spontaneous respiration is restored, which may occur in less than one minute, the infusion should be discontinued.

When the magnesium solution is given intraspinally in a dose of 1 c.c. (25 per cent.) for 10 kilogrammes of body weight to adults, as a rule nothing happens to the respiration. But if the respiration should exceptionally become shallow and slow, the first thing to do is to insert a needle in the spinal canal and let some of the fluid run out and then wash out the canal several times by a warm saline or Ringer solution. This should not be done when a reliable device for artificial respiration is at hand; the spontaneous respiration will return later without this aid, which has the disadvantage that it shortens the period of relief from the spasms.

I consider the pharyngeal insufflation as devised by me and described at the end of this paper, as a most reliable method of artificial respiration in man. Whenever possible, this apparatus should be at hand when a case of tetanus is to be treated. If this is not at hand respiratory paralysis should be treated by inserting a catheter through a tracheotomy wound deep into the trachea, which is to be connected with an oxygen tank. The catheter should be of a size which would fill out about two-thirds of the lumen of the trachea. The oxygen stream should be interrupted a few times in a minute for two or three seconds.

To summarise briefly. Any case of tetanus, mild or severe, should from the start to finish be treated by subcutaneous injections about every six hours with doses of magnesium sulphate as described before. Cases having severe attacks should receive in addition an intraspinal injection. This may be repeated when necessary, but the subsequent doses should be slightly smaller than the preceding ones. If the attack contains an element of immediate danger an intravenous injection may be administered as described above. When for one reason or another the intraspinal and intravenous injections are not practicable the intramuscular injection plus ether anæsthesia may be resorted to. When treating tetanus by magnesium sulphate preparations for artificial respiration ought to be made in order to be able to use efficient doses of the salt. The pharyngeal insufflation device is the simplest and most reliable method for this purpose. When this device is not at hand, then oxygen should be administered by the method of intratracheal insufflation through the tracheotomy wound. The treatment of the failing respiration should be begun at an early stage; asphyxia of the tissues would thus be avoided and a complete restoration could be attained early. The treatment of tetanus by magnesium does, of course, not exclude its serum treatment.

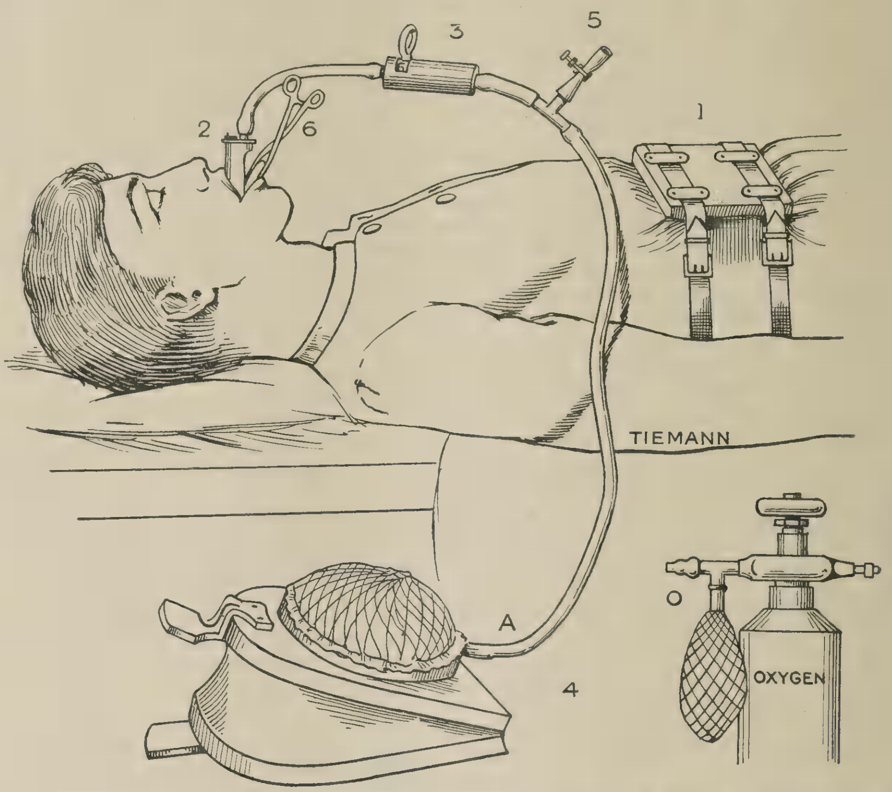
It ought to be borne in mind that unavoidably cases of tetanus will be met with which no method of treatment could cure, either on account of the presence of great amounts of toxin, fixed and free, or on account of the presence of several undiscoverable foci containing living bacilli. The failure to cure such cases should not militate against any method of treatment.

A SIMPLE APPARATUS FOR PHARYNGEAL INSUFFLATION AS A RELIABLE METHOD FOR ARTIFICIAL RESPIRATION IN CASES OF EMERGENCY.

The occurrence of paralysis of respiration after intraspinal injections of too large a dose of magnesium sulphate has been the stimulus for looking for a reliable method of artificial respiration in human beings. It leads up, in the first place, to the now well-known method of intratracheal insufflation. This method, however, can at present be used only by experts and under favourable conditions. During the last few years, while serving on two Resuscitation Commissions, a method for artificial respiration has been developed by me which is easy to handle and reliable in its service. The principle of this method consists of blowing air into the pharynx. If this is done without further precautions, most of the insufflated air would escape through the mouth and through the nose, and would enter into the stomach. The prevention of the escape of air into the stomach is accomplished in our method in the first place by compressing the abdomen. The escape through the mouth and nose is readily prevented by blowing the air through a pharyngeal tube of a proper form and size. The insufflated air, or oxygen, enters therefore nearly exclusively into the lungs.

The mentioned apparatus consists, then, in the first place, of an appropriate pharyngeal tube (which will best be understood by seeing it in the apparatus) and a foot-bellows (or oxygen tank) which serve as a source for driving a continuous air stream into the pharynx. Between the foot-bellows and the pharyngeal tube a "respiratory valve" is introduced which regulates the inspiration and expiration by turning a ring with the thumb from side to side; when turning to the right the air is driven into the lung; by turning it to the left the air from the bellows is cut off, and at the same time an opening is made in the tube through which the escape of the expiratory air is accomplished.

The expiration is carried out through the elasticity of the over-distended chest walls. Between the bellows and the respiratory valve a T-tube is interpolated, which is supplied with a screw clamp on the vertical branch. When the pharyngeal tube is first introduced the T-tube has to *remain widely open;* but immediately after beginning of working the bellows and the respiratory valve the screw clamp should gradually be narrowed down until the chest shows a proper heaving. The mentioned parts of the apparatus should be kept connected and ready for immediate action. Besides these parts, the apparatus contains also a wooden board with belts for the compression of the abdomen; a tongue forceps, some tape, and a stomach tube, to be used in a manner which will be mentioned later. All these parts are collected in a handy small bag. The details and the working of the apparatus are very simple and by seeing the latter the description will be readily understood.



Apparatus for artificial respiration by pharyngeal insufflation. 1. Abdominal pressure pad. 2. Pharyngeal tube. 3. Respiratory valve. 4. Foot-bellows. 5. T-tube with a screw clamp, interpolated between the respiratory valve and the foot-bellows. Pharyngeal tube, respiratory valve, T-tube and foot-bellows should be kept connected by means of good rubber tubing which does not kink. The apparatus will then be in readiness for immediate application. 6. Tongue forceps and tape (or gauze bandage) for tying the tongue to the pharyngeal tube.

Oxygen may be used by attaching the tube (A) to a cylinder of the compressed gas (O) in place of the bellows (4).

The order of procedure should be as follows: 1. The abdomen should be compressed by the small wooden board bearing belts. 2. The tongue should be pulled out by means of the tongue forceps. 3. The pharyngeal tube should be inserted as far back as the pharyngeal wall, with the lateral opening of the tube facing the entrance into the larynx. The tongue should then be fastened to the pharyngeal tube, but not too tight. By this means the entrance into the larynx is kept widely open, and the pharyngeal tube is kept safely in its proper place. The outer end of the pharyngeal tube should then be connected with the end of the respiratory valve which bears the lateral ring. The foot-bellows should be worked continuously, and the respiratory valve should be turned about 12 times per minute. The T-tube should be, as stated above, gradually compressed until a satisfactory heaving of the chest is established. The whole procedure of the establishment of the working of the artificial respiration need not last longer than one minute.

The anterior end of the pharyngeal tube bears an opening which is kept closed by means of a movable plate. Through this opening a stomach tube which fits into the hole can be pushed down until the fenestrated end of the tube is within the stomach. By the aid of this procedure all the air entering into the stomach may escape through this tube, and a very satisfactory artificial respiration may then be obtained even without the pressure upon the abdomen. (The rubber tubing connecting the various parts should be strong and not easily subject to kinking. When the source of pressure comes from an oxygen tank the T-tube should be interpolated between the respiratory valve and pharyngeal tube, to prevent waste of oxygen during expiration, while the rubber bag should be interpolated between the oxygen tank and the respiratory valve for the accumulation of the escaping oxygen during the period of expiration.)

The efficiency of this apparatus has been tested on a great number of animals of various species under complete paralysis from ether and curare without a single failure. It has also been tested in a completely paralysed human being with success. Furthermore, it has been tested in several human beings for the production of profound anæsthesia, and it proved to be absolutely satisfactory even in temporary suspension of respiration.

The pharyngeal insufflation apparatus for artificial respiration can be handled with ease by laymen after slight instruction.

The apparatus, which is made for me by Messrs. George Tiemann and Co., of New York, can be used, of course, for any other emergency case of paralysis of respiration. But it is here especially recommended to have such a reliable and easily handled apparatus on hand when magnesium sulphate is used for the relief of tetanus; then an efficient dose of the salts may be administered without the fear of the consequence of an accident of paralysis of respiration.

A CONTRIBUTION TO

THE STUDY OF THE ETIOLOGICAL FACTOR IN SO-CALLED CEREBRO-SPINAL FEVER.

BY R. DONALDSON, M.A., M.B., CH.B. EDIN., F.R.C.S. EDIN., D.P.H.,
PATHOLOGIST TO THE ROYAL BERKS HOSPITAL, READING, ETC.

THE following paper, the gist of which has already been communicated to the Reading Pathological Society, is the result of observations made during the outbreak of cerebro-spinal fever in Reading. During this epidemic I have examined the cerebro-spinal fluids from about 70 cases, many of which I have seen in consultation with the patients' own medical attendants or on behalf of the Reading sanitary authority.

It has been my great regret that I have had to forego many valuable opportunities for research in relation to this disease. Owing to pressure of work, both military and civil, however, and want of adequate laboratory assistance, I have had my hands full to get through even the routine work. I offer this as an apology for the imperfections in my paper. I would further take this opportunity of saying that any hypothesis put forward by me is based on very scanty grounds, which at a more opportune time must later be carefully examined and amplified. It may then be found that my assumptions require considerable modification.

At the outbreak of this disease I believed, like many others, that the meningococcus of Weichselbaum was responsible for the disease, and, indeed, in every fluid which I have examined a Gram-negative diplococcus has been found and a positive diagnosis made. As has been the case with other workers, I soon noticed that other organisms were present in films made from the centrifuged deposit whose nature puzzled me, especially as in the few cases (five) in which I made cultures from the fluid growths were obtained of what were apparently typical meningococci. These unknown organisms were sometimes coccal in form and Gram-positive. Others were slender Gram-negative rods, while still others, stained by Gram, consisted of minute Gram-positive dots placed a short distance apart as if at either end of a short bacillus. The body of the bacillus was sometimes represented by a faint Gram-negative rod. As a rule this was absent and its apparent site was then represented by a thin streak slightly lighter than the surrounding film. Occasionally one could see masses of these which looked like débris with minute dots interspersed at more or less regular intervals. Occasionally also could be seen several of these dots placed in line at regular intervals from each other, suggesting that there might have been a fine filament connecting them.

With a view of obtaining organisms from the blood of cerebro-spinal cases I withdrew a few cubic centimetres of blood from the median basilic vein of 12 patients at various stages of the disease. The blood was citrated, at once placed in nutrient broth with a + 10 reaction, and incubated for several days. An interval of two or three hours elapsed between the sowing of the tubes and their arrival in the incubator. No growth, to the naked eye at least, took place in any. Subcultures were made on an egg-agar medium devised by workers at the Lister Institute, who kindly gave me the formula. No apparent colonies were grown on these, but owing to the somewhat greater opacity of this medium as compared with ordinary agar it is possible that very minute colonies were missed. This is the more likely as films made from certain of the incubated broth tubes revealed a few organisms more or less similar to what I have described as present in the cerebro-spinal fluid films. It is also possible that while the organisms may have been present in the blood they had not sufficient vitality to continue their existence in artificial media. For more elaborate attempts to recover the organisms seen in the spinal fluid I had no time.

On April 16th I was asked by Mr. E. G. March, of Reading, to see the following case in consultation with him.

CASE 1.—The patient, a young woman, consulted Mr. March on Dec. 14th, 1914, because of an oblong swelling over the extreme surface of the lower part of the left forearm. Naturally it was considered to be a ganglion. The patient showed no signs of tuberculous taint and, indeed, looked unusually strong and healthy. Later Mr. March ascertained that for two months previously to consulting him she had suffered from diarrhœa. On Jan. 4th, 1915, another swelling appeared on the forearm. This was burst subcutaneously under digital pressure. On Feb. 16th the patient took to bed with gastric symptoms. The abdomen at that time was distinctly distended and there was a good deal of flatulence. The temperature was 102° F. in the evening. The urine was of a mahogany colour, but beyond a fairly large amount of indican it contained nothing abnormal. About this time the breathing became rather short, and fluid appeared at the right base with signs of consolidation. The patient complained of pains in the legs and ankles and showed a pyæmic type of temperature. The right lung soon cleared up, but similar signs then appeared in the left lung. Mr. March suspected pus, the infective agent probably having entered through the intestinal tract. Meantime other "ganglia" appeared in various parts of the arms.

On April 17th I made a leucocyte count and found 20,000 leucocytes per c.mm. Of these, 73 per cent. were polymorphonuclear neutrophils. A suggestion was made that the condition was an infective one, and that in view of the history one of the so-called ganglia should be opened and the contents examined. On the 23rd a similar swelling appeared on the tongue. The temperature then dropped to normal, but the pulse remained quick. The ganglia were then opened under an anæsthetic and blood-stained pus was found in every one. I was present at the operation and planted on glucose-agar tubes some of the pus taken direct from the swellings. The leucocytes now numbered about 15,000 per c.mm. The subsequent history so far is that since the operation, now some weeks ago, she has suffered from slight sickness and recently has complained of marked giddiness on moving the head. Pain in the occipital region is marked.

The case was one apparently of pyæmia, with a history of preceding gastro-intestinal disturbance, followed by a prolonged illness, in the course of which we find a high relative and absolute increase in the polymorphs, together with headache, giddiness, and sickness in the later stages. There seems at first sight nothing very much out of the common here, and yet when I came to examine the pus, expecting to find one of the ordinary pyogenic organisms, I received my first surprise. Before referring further to the organism I shall only say that I kept it living by frequent subculture until I had more leisure to investigate it. The desire to make further investigation came with the appearance of the second case, which I shall now briefly describe.

CASE 2.—On May 11th a patient was admitted to the Royal Berks Hospital under Major G. S. Abram, R.A M.C. (T.), with a history that three days previously he was seized with severe persistent headache. There was no history of previous illness beyond the fact that for six years he had suffered from a discharge from the left ear. The temperature was 100·4° F., the pulse-rate 120 and regular, and the tongue was thickly furred. On examination of the ear a slight discharge was seen coming from a small perforation in the membrane; no mastoid pain; teeth very filthy. On the 15th the patient still complained of headache; the pupils were dilated but equal; and there was tenderness in the neck and shoulder, but none over the spine. He could bend his head freely on the chest. There was no Kernig sign. Cerebro-spinal meningitis was suspected, and about 25–30 c.c. of very clear fluid were allowed to escape by lumbar puncture. This was examined in the usual way by making films from the centrifuged deposit. Gram-negative diplococci were found, together with the other unknown forms above mentioned. He was given 15 c.c. of anti-meningococcal serum. On the 17th I withdrew a few cubic centimetres of blood from the median basilic vein, sowed them immediately in about 20 c.c. of ordinary + 10 broth, which was placed at once in the incubator. There was no apparent growth next day, and subcultures were made on 1 per cent. glucose agar. These remained apparently sterile. Subcultures on to fresh 1 per cent. glucose-agar tubes were made on each of the four following days. I kept subculturing because in films made from the broth organisms appeared to be present. On the sixth day I obtained a growth on the agar slope inoculated the day before and shall describe this organism further on. On the 18th there was a slight manifestation of Kernig's sign. The plantar response was flexor, but the knee-jerks were absent. On the 25th a slight systolic bruit was noticed. Next day four teeth-stumps were removed under cocaine. The leucocytes now numbered 15,000 per c.mm. On the 27th the patient became very delirious and attempted to get out of bed. A vaccine made from five different strains of meningococcus which I had isolated during this outbreak was injected. Next day a small dose of an autogenous vaccine made from the patient's own organism was given. On the 29th the abdomen became tumid and the patient rapidly became worse and died.

Post-mortem examination.—The brain and cord showed marked congestion of vessels in the meninges, with some opacity along the larger vessels; a layer of pus on the undersurface of the left temporo-sphenoidal lobe, which also contained a small abscess; and turbid fluid, but no excess in the ventricles. No abscess in the cerebellum. No definite pus in relation to the cord, which was very soft and congested. Skull: Advanced disease of the left middle ear with a perforation through the tegmen tympani, these parts being bathed in pus, while in the middle ear yellowish-white material of a cheesy consistency was found. Otherwise the bones of the skull were apparently normal. Heart: The pericardium contained a larger quantity than usual of turbid fluid. Ante-mortem clot was present in the right auricle. The tricuspid and mitral orifices admitted the tips of four fingers respectively. The myocardium was pale and friable. No vegetations were found. The coronary vessels were healthy, but slight atheromatous change was seen in the aorta in the neighbourhood of the coronary openings. The vessels otherwise apparently were healthy. The bronchial glands were enlarged, hæmorrhagic, and soft. There was a small amount of turbid fluid in each pleural cavity. No sign of tubercle. Small hæmorrhages were found all over the surface of the right lower lobe. In the left lower lobe was found a small whitish nodule which, on being incised, was found to contain pus. No signs of pneumonic consolidation. Abdomen: Liver pale and friable. The kidneys were pale and showed cloudy swelling. No enlargement of the cortex. No hæmorrhage into kidneys or suprarenals. The spleen was enlarged, weighing 1 lb. 6 oz.; no infarcts; no hæmorrhages, but the pulp was very soft and very diffluent. The stomach, small intestine, and appendix apparently were healthy. The colon was greatly distended and contained some light-coloured stools; the mucous membrane showed patches of congestion, but no hæmorrhages and no evident ulceration. Pancreas normal; lumbar and mesenteric glands enlarged; bladder and ureters normal. Muscles: There was a large hæmorrhage into the muscles of the abdominal wall immediately in front of the bladder, into the right iliacus and extending round to the muscles on the right outer side of the pelvis, causing pressure on the right sciatic nerve. The hæmorrhage was probably several days old. A similar but smaller hæmorrhage was found into the muscles of the abdominal wall near the left costal margin. The inguinal glands were enlarged, as also were the glands in the right axilla. These latter were also markedly hæmorrhagic.

The case was remarkable for the high temperatures reached during the illness, 105·8°, 106°, and 106·8° occurring several times, preceded by rigors. This patient during life showed signs and symptoms of cerebro-spinal meningitis, and a Gram-negative diplococcus was found in the cerebro-spinal fluid. Post mortem, however, a temporo-sphenoidal abscess with caries of the temporal bone was found, together with hæmorrhages into the muscles and evidence pointing to septicæmia, borne out by the recovery of an organism or organisms from the blood.

The first point I wish to make is that these two cases, though essentially very different in their history, are nevertheless due to the same infective agent. I am quite aware that the first case, until recently at any rate, never showed any symptom suggestive of cerebro-spinal infection, and that the second case, while showing symptoms of meningococcal infection, will be attributed by some to ordinary middle-ear disease, followed by an abscess in the brain, and I am well aware of the fallacy that may here enter into my argument. However, since completing the preliminary work for this paper, I thought it well to look up recent numbers of the medical journals, and I have received support—or so I think—from papers published on the etiology of the disease,[1] for, so far as I can gather, the organism which I shall now describe appears to be similar in many respects to that described in those papers.

The agar tubes inoculated with pus from the abscesses in Case 1 showed no growth for several days, but about the fourth or fifth day minute colonies were found on the agar. Films made several days later from these showed the most extraordinary diversity of form—club-shaped, pear-shaped, point of exclamation-like, Gram-positive bacilli; small diplobacilli resembling Hoffmann's bacillus; and Gram-positive cocci occurring in pairs or singly with occasional Gram-negative rods and cocci. In addition to these could be seen the small black dots already referred to. Films made from the pus direct showed practically all these forms, the club-shaped bodies apparently having a Gram-negative tail. These cultures were simply kept going for further investigation when Case 2 turned up. I have already described the steps taken to obtain a growth from this case and was surprised to find that the colonies were similar to those of Case 1 when they appeared first. On making films from these I was at once struck by the general resemblance of the organisms to those isolated from Case 1. There were slight differences which I shall describe further on.

Cultural characters.—Owing to the extreme diversity in appearance of the organisms a series of plates were inoculated from each of the two cultures. Within 24 hours on 1 per cent. glucose agar there was a copious growth of colonies on each series of plates. At this stage they were all indistinguishable. They consisted of very minute pin-point colonies, discrete for the most part, with apparently a regular margin, and were rounded or slightly oval in shape. With a low objective they appeared to be homogeneous and granular. They were so small that unless the agar was very clear they could quite easily be missed. Incubated further these colonies grow larger and may attain in a few cases a diameter of about 0·5 to 0·75 mm., though the majority remain smaller.

---

[1] Hort, Shaw, and others: Brit. Med. Jour., March 27th and April 17th and 24th, 1915.

On examination of the larger colonies after several days' incubation, the impression is gained that there are two kinds.

In cultures from Case 2 the colonies were rounded or oval, with a slightly more opaque dot in the centre. The majority had a fairly regular margin, and by the aid of a hand lens the colony looked as if it had a slightly more opaque centre surrounded by a lighter zone, which in turn was surrounded by another rim of the same opacity as the centre. While the majority showed this form there were others which had a distinctly crenated margin. On examination with a low objective they presented the same granular appearance as the former colonies, but differed in that the edge was distinctly "scalloped." The larger colonies were very flat and occasionally a very slightly prominent central boss could be seen. When several days old both types of colony have a dry, glazed appearance.

Colonies from Case 1 showed under a low objective exactly the same granular appearance. When older it was found that the majority did not preserve a smooth unbroken edge. The margin began to show crenation, and in old cultures the edge was very markedly serrated; so much so that there appeared radial divisions running well into the interior and giving the edge a feathery appearance. At the same time there were interspersed with these colonies a few which preserved the smooth edge and were then exactly like the majority of the colonies of Case 2. Except for the feathery edge, colonies from the two cases could not be distinguished with a low-power objective. No growth occurred at room temperature.

Cultures from Case 2 in + 10 nutrient broth after many days' incubation showed a deposit of whitish particles at the bottom and sides of the tube and a slight uneven scum floated on the top. Broth cultures have not yet been made from Case 1. In the water of condensation in agar tubes from Case 1 and Case 2 respectively could be seen minute particles suspended in the liquid. Saline emulsions made from the two cultures differed slightly. That made with a culture from Case 1, while becoming very slightly opalescent, was characterised mainly by the suspension in it of many minute particles or granules. Similar particles were seen in emulsions from a culture in Case 2, but they were not so numerous and the fluid was more opalescent. The same difference was observed in spreading films. The culture from Case 2 seemed to emulsify easily with only a few granules in it, while in that from Case 1 there were more granules and a homogeneous mixture was not obtained. Both cultures suggested the appearance observed in making films from diphtheria cultures, especially that of Case 1. Glucose and saccharose serum peptone water tubes were inoculated from the original cultures from both cases, with the result that glucose in each case was rendered acid while the saccharose remained unaffected. Milk was apparently not clotted by the organism of either case. Cultures were made anaerobically, but no growth was apparent after two days' incubation. Similarly, no apparent growth was obtained after sowing on ordinary + 10 agar and incubating at room temperature. Stab culture in glucose agar showed small granules and discs along the needle track. The organism is fairly long-lived.

Morphology and staining reactions.—Films were made from isolated colonies obtained by plating out and from agar cultures raised from a single plate colony of each of the two types mentioned as occurring in cultures from each case. Gram's and a slightly modified Neisser's stain were employed. A film from a smooth-margin colony from Case 1 showed short and sometimes rather thick Gram-positive rods often occurring as diplobacilli, arranged frequently parallel to one another in small rows. They varied in size and in the intensity with which they retained the Gram stain. They recalled at once the appearance of Hoffmann's bacillus. Others again were club-shaped, or in shape like a point of exclamation. Others appeared to be Gram-positive diplococci of various sizes, sometimes resembling the meningococcus in shape; in other cases the two elements composing the diplo were unequal in size, and sometimes one was Gram-positive while the other was Gram-negative, and occasionally the staining was indefinite. Sometimes these cocci lay singly and then were often oval in shape or slightly pointed at one end. Other diplococci were exceedingly minute, no more than mere specks, and these frequently stained a faint red with Gram and often appeared to have a halo around them. Some appeared to be beaded bacilli, the intermediate parts taking a lighter tint of the Gram. In addition many of the minute Gram-positive dots already referred to were seen, sometimes with a faint red stain joining them; in other cases this connexion was not evident.

In films made from a 12-hour agar growth in addition to the above a short thin Gram-negative rod was seen which sometimes showed strips of a slightly darker red occurring in it. Others had a minute Gram-positive dot at each end. Occasionally also a faint Gram-negative diplococcus was seen. Films from an agar growth raised from one of the smooth-margin type from the culture in Case 2 showed practically the same appearance. Neisser's stain applied to films of the above strains grown on Lorrain Smith's medium showed many bacilli more or less closely recalling Hoffmann's bacillus and staining a uniform red. Others looked exactly like meningococci, while others were short rods with a black bead at each pole. Some were slightly club-shaped and showed black bars transversely to the long axis. While these beaded or barred forms were seen the majority stained red, and in the case of films from the culture in Case 2 while barred forms were seen the majority were coccal, ovoid, or diplobacillary in shape.

Films made from agar cultures raised from one colony of the feathery-edge type from the culture in Case 1 showed forms indistinguishable from the Klebs-Löffler bacillus, with the difference that the film although made from a young culture looked as if it were made from an old diphtheria culture with abundant involution forms. Any illustrated text-book showing involution forms of the diphtheria bacillus will give an idea of what was found here. It is to be noted, however, that along with these forms was found also an occasional thin Gram-negative rod; often a Gram-negative rod lay beside a Gram-positive one. Also a few very small Gram-negative diplococci were seen.

Practically the same appearance was got in films made from a culture raised from a single crenated colony from Case 2. When stained by Neisser it would at once be said that they were films of the Klebs-Löffler bacillus. The smooth-edged type of colony, therefore, would appear to contain a larger proportion of the Hoffmann element, while those with crenated margins had more of the Klebs-Löffler element. In both, however, occasional Gram-negative rods and Gram-negative and positive diplococci and ovoids were seen. When film preparations were made from glucose serum peptone water it was surprising to find the large and irregular forms on the whole absent. The majority were very short diplobacilli, and films made from the two cases could scarcely be differentiated.

Animal inoculations.—White mice were inoculated on May 27th with 1 c.c. of an emulsion in sterile saline of a 12-hour agar culture made from each of the two cases described. For each case two mice were used, one for intraperitoneal and one for subcutaneous inoculation.

Within 20 hours one of the mice inoculated with a culture from Case 2 was dead. The other mouse from the same case appeared to be all right. On the 30th it appeared to be very ill; it maintained the same position all the time, back arched convexly outwards, head touching floor and trembling slightly. On causing the animal to move the trembling became more marked and it walked slowly, dragging one leg after the other. The mere act of touching the animal appeared to increase the tremors. On the 31st it was found dead. One of the two mice inoculated with a culture from Case 1 was found dying within 20 hours. It was lying on one side with its back arched, head down, and toes clenched. Nothing definite was found post mortem. The other mouse inoculated from the same case is still alive and well.

The three mice died from a general septicæmia as the organism was recovered from the heart blood. Films made from the peritoneal fluid, in addition to the variety of form of the organism inoculated, showed large numbers of small Gram-negative diplococci bearing a resemblance to meningococci, also very minute negative diplococci and Gram-negative rods occurring both singly and as diplos. Practically the same findings as in films made from cultures, with the exception that there were many more Gram-negative diplococci.

Two rabbits were inoculated on the same date intravenously with 4 c.c. of the same cultures used for the mice. These rabbits are still well, but seem slightly thinner than they were. Two small guinea-pigs were inoculated on June 2nd subcutaneously into the skin of the abdomen, each with an emulsion in 3 c.c. sterile saline of one agar slope from each case respectively. The age of the agar culture was 20 hours. Both animals are still alive, but that inoculated from Case 1 has some œdema of the lower part of the abdomen, while round the site of inoculation the skin is hard, irregular, and tender on pressure. The hair has disappeared from the part and it looks leathery.[2]

I have said that in every case of cerebro-spinal infection I have found a Gram-negative diplococcus. In every one also I have found two or more of the types of organism just described. In view of that I have stained many of my spare films made from different cases examined during the last three months and have found definite diphtheroid rods present with beading and sometimes with bars. In Gram films made from the various blood cultures in which I was unsuccessful in finding a growth I have been able to distinguish in addition to Gram-negative diplococci one or more of the forms above described. They were evidently present in the attempted cultures and may have grown to a certain extent, but for some reason or other subculture did not succeed. I have found the same types of organism in films made from pus from cases showing definite meningitis. In three cases I have examined catheter specimens of urine, and in two by culture have got the same type of organism. The third one was only examined by film preparations made from the centrifuged deposit and showed again Gram-negative diplococci as well as one or more of the other types. I have observed apparently the same organisms in films made from a case of irregular pneumonia. In this case there appeared to be much larger club-shaped bodies, many with a longer tapering extremity. The same curious variety of form has been got in films and culture from the heart blood after passage through mice.

The factor common to all the fluids and purulent exudates which I have examined is the invariable presence of diphtheroid rods together with Gram-positive and Gram-negative diplococci. All these various types of form have been reproduced in cultures from Cases 1 and 2, and while in culture the Gram-positive elements preponderated, yet on passage through mice large numbers of Gram-negative diplococci were obtained in the peritoneal exudate. These two cases, therefore, I regard as due to the same infective agent as is responsible for the present epidemic, notwithstanding that Case 1 is different from anything I have seen described as due to the meningococcus, and in spite of the fact that Case 2 was complicated by middle-ear disease.

The second point which I now wish to make is this, that in the disease termed "spotted" fever, or cerebro-spinal fever, the causal organism is a pleomorphous diphtheroid rod closely akin to the Klebs-Löffler bacillus, if not a variant of that organism. It is rather fitting that in "spotted" fever, or cerebro-spinal fever, which is characterised generally by the absence of spots, and the absence of typical meningitis in the majority of cases, the paradox should hold good with regard to the etiological factor, so that meningococcal infections are not really due to the meningococcus at all, but rather to an extremely pleomorphous organism. There are various reasons for making this statement, one of which has already been given. Others may briefly be referred to. It has always been a puzzle why such an extremely delicate organism as the meningococcus should be capable of transmission even through a hypothetical series of intermediaries from one case to another frequently at very considerable distance apart. The suggestion now is that we are dealing really with a pleomorphous organism and that the infection is transmitted, not by the meningococcus as such, but by another form in the life-history of the organism which is pretty robust and capable of surviving for considerable periods of time and even under adverse conditions. This form I believe to be a diphtheroid one, although it is always possible that, as Hort and others suggest, there is an ultra-microscopic form. I would put it another way and say that it is probably transmitted in the same way as diphtheria. Subject necessarily to verification by subsequent rigorous investigation I believe the organism to be highly pleomorphous. It would be an extraordinary coincidence if in all these cases whose fluids or exudates I have examined a combination of more or less the same types of organism should be present. Further, the very careful and painstaking efforts of Hort and others to separate out the various forms have met with no success. The explanation is probably to be found in the fact, not that the cultures are impure, but that the organism undergoes various metamorphoses according to circumstances whose nature we do not yet understand. This seems a reasonable explanation in view of the fact that in film preparations great differences in form and staining reaction are frequently evident in the two elements composing a single diplococcus or diplobacillus. Further, we know how extremely pleomorphous is the familiar Klebs-Löffler bacillus, especially in older cultures, and also how in apparently pure cultures of the meningococcus variations in staining, in size, and even in shape have been described. The feature common to both the diphtheria bacillus and the meningococcus, hitherto accepted as being pure strains, is their tendency to variation, more especially of course in the case of the former organism. This plemorphism suggests that after all Hoffmann's bacillus may be merely one of the many forms of the true Klebs-Löffler bacillus. Further, the hypothesis which I suggest would explain to a certain extent the reason for the discrepancies and frequent failures met with in serum treatment.

---

[2] This animal has since died.

If the so-called meningococcus is merely a phase in the life-history of a diphtheroid organism we can understand the effect on the patient of a serum such as Flexner's. Temporary benefit may be expected to follow as a result of its action on the meningococcal forms. The other and presumably the more resistant diphtheroid forms are left uninfluenced. The effect of this wears off, and the patient may be again benefited by the introduction of serum, and so the process goes on until his own tissues overcome the other forms of the infecting organism or until death occurs. My suggestion is that an anti-diphtheroid serum or vaccine, or even an antitoxin analogous to diphtherial antitoxin, may be found to exert a greater influence on the course of the disease than the present antimeningococcal serum, which probably only acts on the so-called meningococcal forms. Further, I would make the suggestion that, if this assumption is correct, the life-history of the gonococcus must be reinvestigated, for, owing to the similarity between the gonococcus and the meningococcus, one might reasonably expect to find a diphtheroid form of the urethral coccus as well. As a matter of fact, various diphtheroid rods are known to be found in that region. It would further explain the very disappointing results obtained by the vaccine treatment of gonorrhœa. The gonococcus may disappear for a time, but returns again, because the vaccine has no effect on the presumably more resistant diphtheroid forms.

If the views above enumerated are correct it would further go to prove the comparative uselessness of examining contacts merely for meningococci. The want of uniformity in the results obtained suggests either errors of technique or the fact that the meningococcus is not always present in the throat as such, but may exist in another form.

Further evidence could be adduced if space permitted in support of the analogy between the manifestations of the disease in the present epidemic and those met with in diphtheria, especially the more malignant forms of it. Within broad limits, seasonal prevalence, presumably incubation period, mode of onset, occasional appearance of rashes, hæmorrhages, and occasionally subsequent paralyses are common to both. The analogy between the two diseases has been remarked upon by several observers both in this and other epidemics. Many of the victims subsequently develop heart affections, and I have now post-mortem notes before me of a case in which the patient died suddenly from heart failure when he was apparently convalescent. Another feature found frequently in cases of diphtheria, as in the epidemic with which we have been dealing, is the comparative slowness of the pulse in relation to the temperature curve. Clinically, in the epidemic mentioned we have seen cases presenting the most diverse symptoms, and many patients must have recovered or died with a wrong diagnosis. I believe the statement quoted by Sir William Osler[3] to be probably very near the truth —viz., that in 2 per cent. of apparently healthy people the diplococcus may be found. I would suggest substituting the words "infective agent" for "diplococcus." Finally, might I make a suggestion that the local epidemics described by McGowan[4] as occurring in industrial schools in Edinburgh and elsewhere may actually have been due to a diphtheroid infection of the type suggested by me and not to a combination of atypical pneumococcal infection occurring in boys the subject of endemic status lymphaticus.

To sum up, I would suggest that the causal organism of the epidemic dealt with in this article is a diphtheroid rod closely related to the Klebs-Löffler bacillus, of which, indeed, it may actually be a variant, and that we are witnessing, as Sir William Osler says, the struggle of a new disease to win a place among the great epidemics of the world. This diphtheroid rod is an extremely pleomorphous organism and may give rise to Hoffmann-like forms, to what appear to be meningococci, &c. It is probably very widely spread in nature in one of its more resistant forms, and it is this form and not the meningococcal one which is transmitted from one to another. It is also probably to be found more frequently among individuals than we imagine. The disease may give rise to the most diverse symptoms, evidently due to an actual invasion of the body by the infective agent, and not merely to the action of toxins manufactured locally. It is in this respect that it differs from diphtheria as we understand it. In other ways, however, there is a certain similarity between the two diseases.

The above hypothesis offers an explanation why sera fail so often in the treatment of so-called cerebro-spinal meningitis, and the analogy to diphtheria suggests that treatment on similar lines should be adopted. It further suggests that fresh investigation must be made into the life-history of the gonococcus, and offers an explanation of the failure of vaccines in that disease.

I am aware that much of the above is open to criticism, but I have already stated that fuller investigation remains to be done when times are more normal than they are at present.

PS.—Since writing the above I find that I have succeeded in obtaining a growth directly from the cerebro-spinal fluid of a fatal case which was otherwise quite healthy and where there was no middle-ear disease. I have also obtained a growth from the blood of another case sent me by a pathologist, and I have seen organisms, morphologically similar to those described, in films made from the pleural fluid. These facts are further evidence in favour of the sameness of the organism causing the present epidemic.

Reading.

[4] Endemic Febrile Illness with Rapidly Fatal Cases Occurring in a Boys' Industrial School, Proceedings of the Pathological Society of Great Britain and Ireland, January, 1913, p. 412.

HEALTH OF NEWQUAY (CORNWALL).—Dr. A. Hardwick, the medical officer of health of Newquay, in his twenty-sixth annual report, states that during 1914 the death-rate was 10·2 per 1000; the birth-rate was 11·0 per 1000. Newquay has increased rapidly, probably more so than any other town in Cornwall. In 1871 the population was 1121, and now it is estimated at 4850.

SEVERE CASE OF
INTRACTABLE SYPHILIS TREATED SATISFACTORILY WITH HECTINE.

C. H. MILLS, M.R.C.S., L.R.C.P. Lond.,
TEMPORARY LIEUTENANT R.A.M.C.; MEDICAL OFFICER IN CHARGE OF SYPHILIS WARDS, MILITARY HOSPITAL, ROCHESTER-ROW, S.W.

Private ——, aged 30, was admitted to the Military Hospital, Rochester-row, London, S.W., on Sept. 19th, 1914, suffering from a large perforation of the hard palate. He was placed on the syphilis register after giving the following history.

History of case.—The patient, a reservist, had been a very heavy beer drinker. In November, 1910, he developed a hard chancre on the penis. He did not seek medical advice, however, until after the chancre had been present for three weeks. He then consulted a civilian doctor, who commenced a course of mercurial treatment comprising pills and medicine by the mouth. This he continued for six months. Three weeks later, having abandoned his treatment, a rash appeared on the trunk, arms, and legs, which he described as dry and scaly. The patient then went to a large general hospital when scabies was diagnosed, and he was given sulphur ointment supplemented by sulphur vapour baths, and the rash gradually disappeared. In 1913 (two years ago) a "lump" appeared in the centre of the hard palate. He attended the Mildmay Mission Hospital, when he was again given mercurial pills and mouth wash. He continued his work for four months, and the condition seemed to improve. The gumma, however, for such it was, did not discharge nor was the surface broken. Eight months later (approximately one year ago) the gumma again commenced to increase in size. This he reported to the Mildmay Mission Hospital. It had now broken down and was discharging profusely. Mercurial treatment was resumed, but the ulcer progressively got worse for a period of six months. An operation was now suggested for the removal of the necrosed bone. At this date, however, he was called up to the colours as a reservist, and after completing one month's service (including three weeks in France) he was sent to the Rochester-row Military Hospital for treatment.

Condition on admission.—The patient was in a flabby, unhealthy condition, presenting an oval perforation of the hard palate roughly the size of a shilling, through which was exuding a foul yellow discharge, and his breath was very foul. There were no external gummatous changes elsewhere about the body. The nervous system was unaffected, as evidenced by normal reflexes. Weight, 12st. 4½lb. There were no albumin and no signs of hepatic cirrhosis. The heart and chest were normal.

Treatment.—A combined course of salvarsan intravenously, accompanied by mercurial injections intramuscularly, was decided upon. Accordingly the patient was given three intravenous injections of 0·9 grm. neosalvarsan, administered at intervals of a fortnight, accompanied by ten weekly injections of 1 gr. mercurial cream, during which course his weight dropped to 11st. 3lb. He was now put on pot. iodid. gr. 7 three times a day and daily inunctions of ung. hydrarg. drm. 1. The pot. iodid. was gradually increased until 15 gr. four times a day were tolerated without any ill effects. The discharge through the perforation, however, was so foul that the patient had to be isolated. The perforation gradually increased in size—this three months after admission to hospital. The following necrosed pieces of bone were removed during this period at intervals: the whole of the vomer, the perpendicular plate of the ethmoid, and the palatal process of both the palate and the superior maxilla of the right side. The Wassermann reaction was positive. It was now deemed advisable to adminster an injection of 0·6 grm. of the original salvarsan, which was tolerated without any reaction, pot. iodid., now 20 gr. four times daily, accompanied by daily mercurial inunctions, being continued. For about ten days the destructive processes appeared to be no longer progressive. The patient now developed alarming attacks of vomiting, and so a diet consisting of small quantities of milk at short intervals was resorted to. The lower lid of the right eye became very œdematous, accompanied by almost alarming protrusion of the palpebral conjunctiva. It was considered possible that the patient was being overtreated and a rest of two weeks was ordered, during which time, however, the œdema, if anything, became more marked. No exophthalmos. Vision in that eye was rendered impossible, unless the lids were separated. The sight then, however, was found to be normal. The lacrymal duct was occluded, and bony crackling could be demonstrated when pressure was made over the right lacrymal bone, in which region a discharging sinus appeared. The first molar tooth on the right side was extracted from the upper jaw, and the antrum, which now possessed no inner wall, thoroughly irrigated. Necrosed bone was at the same time removed, comprising the outer wall of the alveolar process and part of the malar bone, thus opening up the antrum external to the alveolar process. A leech was applied to the œdematous lower lid followed by fomentations for six hours, which reduced the swelling very satisfactorily.

At this stage it was decided to try a course of hectine injections, with which the French syphilogists have claimed such good results. Accordingly ten subcutaneous injections of 0·2 grm. were given, the first three on alternative days followed by seven daily injections. The patient's condition commenced to improve almost at once and the vomiting ceased. The discharge became less, and the appetite improved. Nobody was more impressed than the patient himself, who at this period had become very despondent. In the first week his weight increased 7 lb., and at the end of the course of ten injections he was allowed to sit up.

Encouraged by the very satisfactory results of this first course of ten injections, a second course was commenced on March 11th, 1915, comprising ten daily subcutaneous injections of 0·2 grm. hectine in the buttock. During this course the patient increased in weight by 7½ lb. After a fortnight's rest a third course, also comprising ten daily subcutaneous injections, was administered, during which he increased exactly 5 lb. The gross gain in weight from prior to the hectine courses is indicated by the increase from a minimum of 10 st. ¾ lb. up to 12 st. 8 lb.—i.e., 2 st. 7¼ lb.

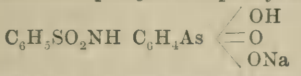
Present condition.—As can be surmised from the increase in weight, the general condition of the patient now is extremely satisfactory. His appetite is normal, and he takes his daily exercise round the hospital quadrangle; he is anxious to resume general duties. The huge cavity resulting from the total destruction of the structures comprising the nasal fossæ is lined with healthy granulations. There is a bridge of healthy gum separating the orifice external to the alveolar process and the perforation of the hard palate. There is now no discharge coming down into the mouth, and the sinus over the right lacrymal bone is healthy. It is considered wise to keep the patient on a modified course of pot. iodid. and mercurial inunction.

The case is interesting in that it clearly proves that we have, apart from the already accepted specifics comprising mercury, pot. iodid., salvarsan, neosalvarsan, and now kharsivan, neokharsivan, and the French arsenobenzol, "yet another valuable string to our bow." In this case we have not the least doubt that but for the employment of hectine this patient's chance of ever becoming an efficient soldier, or, in fact, of ever recovering—his decline in weight and general condition being so rapid—was very poor. It was a matter of daily anxiety as to how much further the processes would go without involving the meninges. This is undoubtedly unique in our experience in the most severe cases of syphilis treated at this hospital, in that no improvement resulted when subjected to the above described intensified combination of accepted specifics. Regarding the patient's future service in the army, he is merely waiting now for the general structures of the buccal cavity to have settled down sufficiently to warrant the fitting of a dental obturator.

Encouraged by the above, we have used hectine in other cases, and hope to publish more notes on the subject before long, and discuss its relative value with the results we are obtaining with kharsivan and neokharsivan, which drugs we are now giving an exhaustive trial in approximately 100 cases.

The following formula gives the composition of hectine:—

Sodii Benzo-Sulpho-*p*-Aminophenyl arsonas.



$$C_6H_5SO_2NH\ C_6H_4As\begin{cases} OH \\ =O \\ ONa \end{cases}$$

Hectine consists of colourless needles, very soluble in water, containing approximately 21 per cent. of arsenic. The preparation used is put up in sterile ampules containing 20 cg. in 1 c.c.

Hitherto we have employed hectine purely locally—e.g., into the neighbourhood of a chancre, gumma, &c.—with good results clinically.

CENTENARIANS.—Mrs. Mary Shelton, of Rowcroft, Stroud, Gloucestershire, celebrated the 103rd anniversary of her birthday on May 29th.—Mrs. Jane Taylor, who was over 100 years of age, has recently died at Burlescombe, Devon.

DEATH OF MR. FRIEND EDWARD STREETEN.—Mr. Streeten, L.R.C.P. Edin., M.R.C.S., D.P.H., died recently at Swindon, in his sixty-third year. He received his medical education at St. George's Hospital, and in the "eighties" began practice at Swindon. After some years he gave up his private work and devoted his whole time to his various appointments. He was medical officer of health for the borough of Swindon and for the Highworth rural district, and was also medical superintendent of the Swindon and District Isolation Hospital, and school medical officer for the Swindon education committee. He was one of the best-known men in Swindon, taking an interest in all local matters, and was held in great esteem there. He was an energetic Freemason, and at the time of his death was Acting Provincial Grand Secretary. He leave a widow and two daughters.

VACCINES IN THE TREATMENT OF RESPIRATORY DISEASES.[1]

BY ROBERT J. ROWLETTE, M.D. DUB., F.R.C.P. IREL.,
PHYSICIAN TO JERVIS-STREET HOSPITAL, DUBLIN.

WITHIN the past few years vaccines have been gradually coming into more frequent use in the treatment of diseases of the respiratory tract. Our knowledge as to their applicability and its limits is still to a great extent tentative, and it is only by the accumulation and comparison of the experience of different observers that we can hope to advance our knowledge. I do not, in the present paper, intend to concern myself with diseases due to tuberculous infection.

In the early days of vaccine treatment it was thought that its scope was limited to localised diseases, and in particular to those of chronic course. We know now that neither the degree of acuteness nor the lack of localisation is a bar to successful treatment, and some of the most marked successes have been in the case of acute generalised diseases. The main difficulty of vaccine treatment is one of diagnosis—of bacteriological diagnosis, and this difficulty is specially great in the case of diseases of the respiratory tract. No clinical entity among the diseases of the respiratory organs—not even pneumonia—can be stated with confidence to be due to a constant bacterial cause. Pneumonia, though most commonly due to the pneumococcus, may be due to any one of half a dozen organisms. A similar statement would be true of the infective diseases of the rest of the respiratory tract. We cannot, therefore, foretell from clinical grounds what organism we have to deal with in any particular case.

But this is only the beginning of our difficulties. The respiratory tract is part of the surface of the body, and it is open to constant bacterial soiling. In the upper part of the tract the mucous membrane is the normal habitat of a great number and variety of organisms, many of which are potentially pathogenic. In case of chronic infection the number of organisms may be indefinitely increased, and two or more of them may be simultaneously pathogenic. Our problem is, therefore, not merely to discover the organisms present, but to select from among them that which is most likely to be causative, bearing in mind that more than one may be causative at the same time. With our present degree of knowledge of the bacteriology of the respiratory tract it is not easy to solve the problem. Indeed, in not a few cases the diagnosis is only settled by the result of treatment. This, however, is not peculiar to vaccine treatment.

This difficulty of diagnosis might not, it is true, be a great hindrance if we were merely engaged in studying a scientific problem, where we had ample time and material at our disposal. It is very real, however, in the conditions of practice, whether in hospital or in private. It is not easy to subject a patient to several series of inoculations with different organisms, (*b*) being employed when (*a*) has proved useless, and (*c*) in its turn replacing (*b*). It is by an increasing knowledge of the relations of the several organisms which inhabit the respiratory tract to definite diseased conditions that vaccine treatment will be rendered at once more widely applicable and more efficacious in these diseases. When we are able to make as certain a bacteriological diagnosis of the cause of an infective lesion of the nose, throat, or bronchi as we are of the cause of a boil, vaccine treatment of respiratory diseases will be simple. In the meantime we have high authority for believing that "probability is the very guide of life," and the same authority advises us, in matters of practice, to consider ourselves under an absolute and formal obligation, in point of prudence and of interest, to act upon a presumption or low probability, though it be so low as to leave the mind in very great doubt which is the truth.[2]

---

[1] A paper read before the Section of Medicine, Royal Academy of Medicine in Ireland, on May 21st, 1915.

Where no such presumption or probability can be found the question arises whether it is better to treat with one organism only or with a combined vaccine. The former is the more scientific method, and is the line I usually prefer. If, however, treatment produces no effect in a reasonable time, then the presumption in favour of the selected organism diminishes and may disappear, and another must take its place. In the conditions of practice, however, one cannot always choose the most scientific method, and in many cases one must from the start use a mixed vaccine, or, as I prefer, combined treatment by two or more vaccines. But the difficulties of administration are thereby greatly increased.

In vaccine treatment two points are essential: (1) proper dosage; and (2) suitable periods. It is not always easy to form a just judgment on these points, even with a simple vaccine, and when two or more vaccines are employed simultaneously the difficulties are greatly increased. It is impossible to analyse the effect and to assign to each vaccine its proper share. Where the infection is truly mixed the negative phase of one organism may interfere with the positive phase of another, and the results are inextricably entangled. When, however, it is necessary to treat with more than one organism it is better to keep the vaccines separate than to use a mixed vaccine. By doing so one can keep a certain control of the respective doses, and one can at any rate give the vaccines at approximately suitable intervals.

Something can be done to simplify the problem of diagnosis by care in the collection and examination of material. As the seat of disease may be either the nose, the naso-pharynx, the larynx, trachea, and bronchi, or the lungs, our methods of collection will naturally vary. If the material is to be collected from the nose the orifices of the nostrils should be well washed with soap and hot water, and swabbed with a pledget of wool moistened with alcohol. The patient, closing one nostril, should then blow his nose forcibly into a wide-mouthed sterile bottle; the process should then be repeated with the other nostril. If the bacteriological examination can be made without delay a sterile wipe or handkerchief may be substituted for the bottle, but the danger of contamination from the skin is greater.

In the case of the naso-pharynx, throat, or bronchi attention must first be paid to the cleansing of the mouth. It should be well rinsed with hot sterile water and the teeth thoroughly brushed. The patient is then directed to hawk or cough, as the case may be, and to spit into a sterile flask. In the case of the naso-pharynx, if secretion be plentiful, a culture may readily be obtained direct from the throat by the help of a platinum loop or a sterile swab. When the patient is entrusted with the collection of the specimen himself he should be directed to collect it first thing in the morning. In every case enough material must be obtained to permit of direct examination of smears as well as of cultural investigation.

Sputum, from whatever source and whatever may be the methods employed in collecting it, should, before cultures are made, be cleansed by washing in clean water. A convenient method, devised, I think, by Dr. W. E. M. Armstrong, is to put the sputum in a gauze strainer, such as is used on the tea-table, and hang it for some time under a slow-flowing tap. This superficial washing will almost certainly wash off any organisms which merely adhere to the sputum, while it will leave behind those which have accompanied it from its source.

The next step is the examination of direct smears, and from the study of these smears more than from the cultures one forms opinions as to the relative importance of the organisms present. A preponderating number of one organism is important, but weight must also be given to the known causative power of each. The presence of an organism not known to be normally present in the region under investigation must receive special attention.

Cultures are next made. I rely almost entirely on agar and blood-agar plates and on broth tubes. The blood-agar is of particular use in the isolation of the streptococcus and the pneumococcus.

I next proceed to discuss the results obtained in treatment of various conditions. I only purpose dealing with cases in which the treatment was given to such a degree as to permit of some judgment being formed as to its effects. I exclude, therefore, a number of cases in which its use was desultory or haphazard, as also a number in whose treatment I have only had a consultative or advisory duty. Some, however, are included in which, though a trial was given, it was hardly sufficient to come to a final judgment. The series finds itself reduced by these weedings to 14 cases. They were as follows: Chronic naso-pharyngeal catarrh, 4; recurrent acute naso-pharyngeal catarrh, 4; recurrent acute general catarrh with bronchitis, 3; chronic bronchitis, 2; and pulmonary abscess, 1. The 4 cases of chronic naso-pharyngeal catarrh were of long standing, and all the patients had undergone local surgical treatment of various kinds. The infections were: in 1 case pneumococcus, in 1 pneumococcus and micrococcus catarrhalis, in 1 streptococcus, and in 1 staphylococcus aureus and streptococcus. The dosage employed was pneumococcus, 10–60,000,000; micrococcus catarrhalis, 50–200,000,000; streptococcus, 10–25,000,000; and staphylococcus aureus, 50–500,000,000. The number of injections varied from 6 to 18. The results in three of the cases were entirely satisfactory; in the fourth the treatment had no effect. In Case 1, that treated by the pneumococcus alone, the condition had been very severe and protracted. The patient was unable to breathe through his nose, and at night the catarrh was so severe that he could not sleep more than a few minutes at a time. He used a dozen handkerchiefs in the day. Progress was steady, and after ten injections all his symptoms had disappeared. In Case 2, treated by streptococcus, relief was obtained at once, and only six injections were required. It is possible that this patient will need a further course. In Case 4, in which staphylococcus aureus was found, the treatment failed. This was a surprise to me, as the presence of a definite pathogenic organism such as staphylococcus aureus in the pharynx and nose offered good hope of cure; a further course with the streptococcus, which was also present, gave no result.

---

[2] Bishop Butler: The Analogy of Religion, Introduction.

Four cases of acute recurrent nasal catarrh were treated. In 2 the infection was of micrococcus catarrhalis, in 1 of streptococcus, and in 1 of staphylococcus aureus. In Case 5 the nasal catarrh recurred nearly every evening, and was, I believe, dependent on pyorrhœa, for which condition the patient was sent to me for treatment. The vaccine was made from the pus of the gums, and it was only after a few injections had been given that I learned of the catarrh by the patient asking me whether the injections could have cured the condition, from which he unexpectedly found himself free. He had one or two relapses, but on the cure of the pyorrhœa the catarrh disappeared. In treating nasopharyngeal conditions it is always necessary to search for pyorrhœa and to insist on adequate local treatment. Case 6 was that of a barrister very active in political work, who had frequently to speak in the open air, with the constant result that a violent attack of catarrh came on, and he spent a sleepless night. The condition had persisted for nine months. In all he got 11 injections, varying from 50–150,000,000 micrococcus catarrhalis. He became perfectly well, and has remained so for three years. Case 7 (streptococcus) was that of a colleague who suffered much from sudden severe attacks of catarrh lasting a day or two, and recurring every few weeks. He did not permit me to carry out the treatment systematically, because after two injections of 10,000,000 he remained free from trouble for three months. One or two slight recurrences were easily relieved by further injections. Case 8, of staphylococcus aureus, was one of so-called "hay fever" occurring in a naval officer. He suffered from it every dusty day in summer whether in town or country. He never had it in winter or at any time afloat. He received four injections in July, 1913, and remained entirely free from catarrh, though ashore, for the rest of the summer. In 1914 he had a relapse, but I do not know the result of the treatment which was then resumed.

Of the 3 cases of acute recurrent general catarrh, 2 were infections of micrococcus catarrhalis and 1 of a staphylococcus. In Case 9, of micrococcus catarrhalis infection, the patient received eight injections, varying from 7–20,000,000, with the view of giving an immunity against future attacks. The course was given during the winter months, and the patient had no attack after the first injection. She had, however, a recurrence the following winter, and no permanent good resulted. I think that the doses given were too small. In Cases 10 and 11 the patients were "always catching cold," as they put it. Short courses of four injections of a staphylococcus and two of micrococcus catarrhalis respectively have given them satisfactory protection for the past nine months.

I have only treated two cases of chronic bronchitis, one with micrococcus catarrhalis and one with streptococcus. I do not think that either case was benefited to any appreciable extent, but in neither case was a sufficient trial given. One of these patients has just asked me to treat him again by the same method.

The last case in the series was one of abscess of the lung. A young woman, aged 26 years, after the operation of removal of the tonsils and of adenoids in the end of June last, developed signs of inflammation in the lower lobe of the right lung. She was put under the care of Dr. T. G. Moorhead, and subsequently, during his absence from Dublin, of my colleague Dr. F. X. Callaghan. The inflammation pursued a varying course for some four weeks; consolidation occurred, followed by abscess formation. The diagnosis was confirmed by the help of the X rays. The expectorated pus was examined, streptococcus and a staphylococcus being found. Vaccines were prepared, and doses of 5–10,000,000 of the one, and 25–50,000,000 of the other given at two-day and four-day intervals. A few doses of antistreptococcus serum were also given. The only other active treatment was the use, on Dr. Moorhead's advice, of an inhalant containing formalin, chloroform, menthol, and pine oil. This undoubtedly helped to empty the cavity and thereby to diminish toxæmia. For three weeks (up to August 28th) there was no improvement and the cavity extended, becoming easily mapped out by percussion on the anterior chest wall. The propriety of operation was discussed from day to day, when improvement began and (on Sept. 4th) the temperature settled to normal. For a long time the cavity was very obvious by percussion and auscultation, "cracked-pot sound" being very marked, and cough persisted throughout the winter, but otherwise the patient's health was good. I had the opportunity of examining her again a few weeks ago. The cavity is much shrunken; it cannot be detected by percussion, though cavernous breathing is heard; there is apparently a fair amount of fibrosis round the cavity; there is still some cough, but the expectoration is not foul. The patient's general health is excellent. I cannot attempt to assign to each part of the treatment its proper share of credit, but the prospect at one time seemed hopeless or nearly so, and the result has been very satisfactory.

I have not included in my series any cases of any form of pneumonia other than that just related, since in no other have I applied the treatment systematically. It appears to be of little use to employ vaccines in the treatment of pneumonia unless the case comes under observation very early, an event which rarely happens.

Taking my series as related, in 10 of the 14 cases treated the result was very satisfactory; in 1 there was a temporary improvement, and in 3 no result could be traced. In 2 of these latter I am not satisfied that the trial was adequate. Classifying the cases treated according to infection the results are as follows: micrococcus catarrhalis 5, of which 3 became quite well, 1 was benefited and 1 unaffected; pneumococcus 2, both became well; staphylococcus 1, became well; streptococcus 3, of whom 2 became well, and 1 was unaffected; streptococcus and staphylococcus 2, both became well; staphylococcus aureus 1, became well.

When one remembers that many of these conditions had already proved their obstinacy, and that ordinary methods of treatment of chronic respiratory diseases are of very little avail, I think it may be claimed that the results of vaccine treatment are distinctly encouraging.

Dublin.

X RAY LOCALISATION AND THE REMOVAL OF FOREIGN BODIES ON THE X RAY TABLE.

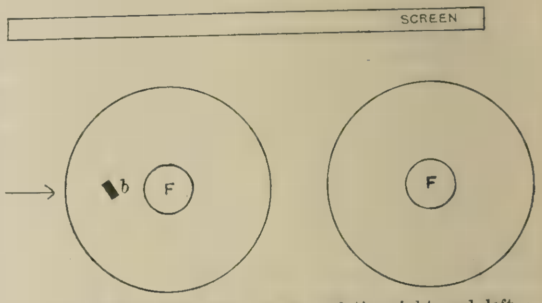
BY JOHN R. CALDWELL, M.B., CH.B. ST. AND.,
LIEUTENANT, ROYAL ARMY MEDICAL CORPS (SPECIAL RESERVE).

IN these days one rarely glances through a journal of surgery without finding a description of some "new" method of localising foreign bodies. These are nearly all modifications of the classical method of Mackenzie Davidson, and the principle underlying them all is the same. The majority have as their object the determination in inches or centimetres of the depth of a foreign body in the tissues. The radiographer thinks he has done his duty when he has stated that below a certain mark on the skin at a certain depth will be found the foreign body in question. There is at present a tendency to overestimate the value of such information. The almost unattainable ideal is an anatomical localisation. Stereoscopy aims at such, but unfortunately the same picture is differently interpreted by different observers, and there are numerous inexplicable fallacies in the method. I repeat that the value of X ray localisation in units has been overestimated, and that to be really useful the information provided by the radiographer should be in units; yes, but should also give an idea of the relations to neighbouring structures. It has been suggested[1] that an atlas of transverse frozen sections of the human trunk and limbs might provide useful information upon which to use the data of "stereometry," but as the tissues vary so much in thickness and as there are so many sources of error the value of such would be very doubtful. To this there is the exception of the eyeball, which varies in dimensions within limits so narrow that the cross-thread localiser of Mackenzie Davidson has been of untold value.

Some time ago I had on the X ray table a patient, paraplegic, in whom a bullet was found in the lumbar region 1 centimetre to the left of the spinous process of the fourth lumbar vertebra. The wound of entrance was slightly to the left of the second lumbar spine, and there were indications of fracturing of the lamina of that vertebra. Localisation by a simple method revealed the fact that the bullet lay at a depth of $4\frac{1}{2}$ centimetres, and the question to be decided was whether the bullet lay in the canal or dorsal to the lamina. Clinically the paraplegia suggested the former, but, of course, it was conceivable that the bullet having fractured the lamina of the second lumbar vertebra had glanced down and lay separated from the canal by the thin plate of bone. It will be at once understood that a variation in the thickness of the tissues overlying the spinous process, or in the length of that process by about half a centimetre (i.e., the thickness of a lamina), made all the difference as to whether the bullet lay in or out of the canal. Obviously the data supplied were little if any help.

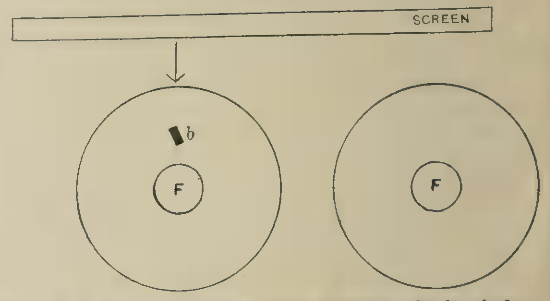
Where is the radiographer who has not, without over-fatiguing his mental faculties, thought out for himself a method of localising foreign bodies, but of what real value is a very exact measurement? When the surgeon has discovered the bullet it may be found that the radiographer was correct to within a few millimetres, yet before the commencement of the extraction the information given could at the most give a very imperfect idea of the whereabouts of the offender. Thus it is that the surgeon has called to his aid the "telephone probe," and some enthusiasts have gone so far as to say that in the near future no surgeon will attempt the removal of a foreign body without its aid. A probe, whether telephone or otherwise, is a bad instrument at least in recent or septic cases, and in a war hospital it may safely be dispensed with. Operating surgeons will be only too ready to agree that localisation still leaves much to be desired, and for reasons some of which have been given above.

FIG. 1.



This figure illustrates sections, say, of the right and left thighs with a bullet (*b*) to the outer side of one. The arrow indicates the position of the incision and the plane of the forceps parallel to the screen. F, Femur.

FIG. 2.



Illustrating sections as before, and showing a foreign body (*b*) in front of the femur (F). The arrow indicates the position of the incision.

The method of removing foreign bodies on the X ray table while not overcoming these ills holds so many advantages that it becomes impossible for an experienced operator to fail in the removal of one in an accessible situation. The advantages of being able to see the object of the search whenever you please are enormous, and this, combined with the intelligent appreciation of the principles of radioscopic localisation as described in my last two communications on this subject,[2] makes a tremendous difference on the speed of an extraction and the certainty of success.

But it must not be supposed (as happens here frequently among those watching an operation) that it is as easy as it looks, and here I may be permitted to mention how difficulties arise in this method of working. In the first place, it is not possible on the X ray table to put your patient into all the positions permissible on the ordinary table for the reason that the screen must always be considered. In operating on the upper part of the thigh the patient must be either on his back or his face in order that the opposite hip may not interfere with the screen. Likewise, in an operation on the side of the chest or axilla, you must choose the diameter which gives the best view, and, again, the position must be dorsal or ventral. Here arises the difficulty. If a bullet, for example, be situated on the outer aspect of the upper end of the thigh the forceps must approach it in a plane parallel to the plane of the screen. (See Fig. 1.) Where it is possible to make the incision over the apparent position of foreign body on the skin the operation is a matter of seconds, as it is practically impossible with the foreign body carefully "centred" to miss it. (See Fig. 2.)

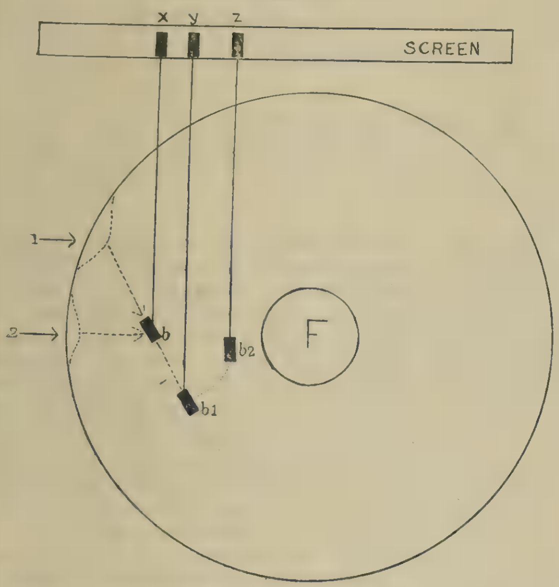
---

[1] Some Principles of X Ray Localisation, W. Cotton, M.D., Practitioner, April, 1915.

[2] The X Ray Theatre in War Hospitals, THE LANCET, April 24th, 1915, p. 854; Report on a Few Cases illustrating the Removal of Foreign Bodies on the X Ray Table, THE LANCET, May 15th, 1915, p. 1018.

How, then, are we to find the most suitable site for the incision in cases such as are diagramatically represented in Fig. 1? The method which I adopt might be described as that of "transmitted impulse": the part concerned is systematically "prodded" with either the finger or forceps under the rays, and the movements of the foreign body are studied. For this purpose I use the business end of a pair of "Spencer Wells" forceps. Working systematically from above downwards in a plane parallel to that of the screen, impulses are conveyed *viâ* the soft parts to the foreign body, and when the point of maximum movement or excursion of this is attained the corresponding position on the skin is noted. Here, if possible, the incision should be made, but if this is not convenient the near vicinity should be selected. The sudden increase in the excursion of the foreign body noted on reaching the correct lateral plane is diagrammatically explained in Fig. 3. This method, though apparently unscientific, is astonishingly accurate. A little experience will indicate the cases to which it is applicable, but briefly these are the upper part of the thigh, the side of the chest wall, the axilla, the scalp, and the face. Small foreign bodies in the scalp and face can be well located in this way. The head under the screen is slowly rotated, so that merely the thickness of the tissues overlying the bone can be inspected. When the foreign body is seen it can be located by the method just described. Here it is now a rule to remove all fragments, however minute (within reason). Many might be well left alone, but occasionally as a result unpleasant things happen. A considerable time ago I had a patient in whom the side of the face was "peppered" with minute pieces of shell. These were thought to be so trifling that it was decided merely to apply fomentations. Intense œdema of the eyelids and conjunctiva supervened, which only ceased with the removal of a minute foreign body which had slightly splintered the external angular process of the frontal bone.

FIG. 3.

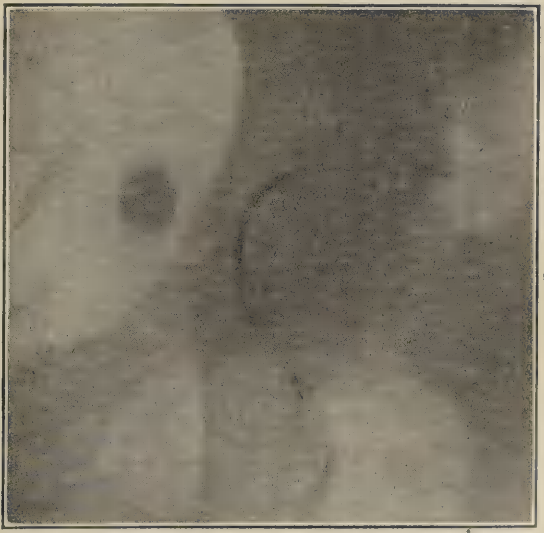


The figure represents section of the thigh; F, femur. Impulses delivered *viâ* the tissues to the foreign body at positions 1 and 2 may cause an equal amount of actual movement thereof. The apparent movement on the screen is, however, much less in 1 than in 2. The sudden accession of movement seen on reaching the correct lateral plane is thus explained. (For purposes of simplicity the rays are represented as being parallel.)

b, Foreign body in resting position. b_1, Foreign body after impulse at 1. b_2, Foreign body after impulse at 2. Screen: X-Y = Apparent distance travelled by *b* on delivery of impulse at 1. X-Z = Apparent distance travelled by *b* on delivery of impulse at 2.

The method of removing foreign bodies on the X ray table is thus not a substitute for localisation but a combination of localisation and extraction. In difficult situations I still employ stereograms as accessories, but detailed measurements are never made. Foreign bodies in the near neighbourhood of bones are easily removed because their position with regard to fixed landmarks is easily and accurately given. In this method, as will be understood from my earlier communications, the forceps point constitutes a fixed point of known position, and the study of its movements relative to those of the foreign body constitutes the secret of the speed and success of the method.

FIG. 4.



Showing foreign body in the neighbourhood of the ischial spine.

Two cases upon whom I operated recently are of sufficient interest, I think, to justify description. They exemplify in a striking manner all that has been claimed for this method. Both showed old and healed wounds, and it is always a matter of the greatest difficulty in these to decide if their complaints are real, imaginary, or assumed. In any case the quickest way usually to get them back to the firing line is, if possible, to remove the source of the trouble.

CASE 1.—A Belgian private in the 2nd Carabiniers was wounded by a shrapnel ball at Werchter, near Louvain, on Sept. 12th, 1914. He was sent to the military hospital at

Antwerp, then to hospitals at Ostend, Portsmouth, and Bournemouth. When at Bournemouth he had an operation lasting three hours without success. There he was kept for four and a half months and then returned to his depôt in France, after which he was sent to us to have the ball removed.

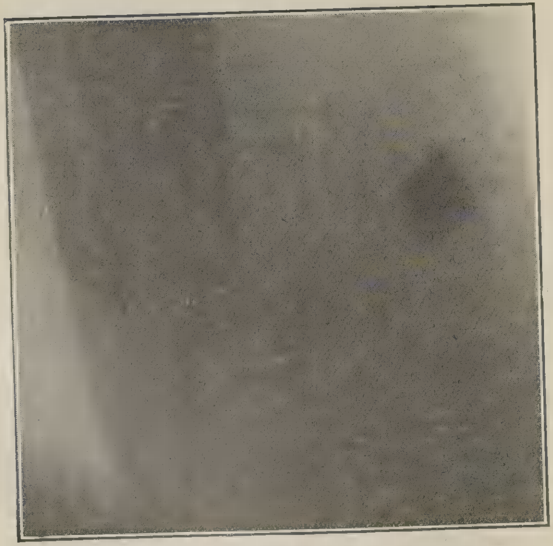
Upon admission he was somewhat lame and complained of pain on walking and inability completely to extend his thigh. Examination revealed the cicatrised wound of entrance on the left buttock 1 inch to the left of the middle line and 2 inches behind the rectum. There was an old operation scar on the buttock some 4 inches long. On being put on the radioscopic table he sarcastically remarked that this was the eighth time and would probably be as fruitful in results as the others. The radiogram revealed a ball in the neighbourhood of the ischial spine. (Fig. 4.)

At the operation under spinal anæsthesia an incision 2 inches long was made alongside the old one and the fibres of the gluteus maximus were exposed. Under the rays a pair of long closed forceps were pushed down and the ball grasped and extracted. The operation lasted 14 minutes. At the moment of writing (the fifth day) the patient is walking in the garden of the hospital.

CASE 2.—A private in the Grenadiers, wounded on the same day and at the same place as the preceding patient, was treated at hospitals in Antwerp, Ypres, Havre, and Tours. Radiographic examinations were made on seven different occasions, but no operation was attempted.

On admission here the patient was somewhat lame and complained of pain in the lower part of the thigh. Upon examination the cicatrised wound of entrance was found on the outer side of the thigh at its middle. The radiogram (Fig. 5) revealed a flattened-out shrapnel ball embedded in the hamstring muscles and a second one lying in the medullary cavity of the femur. The opening in the bone made by the ball in its passage is seen some 4 centimetres above the ball.

FIG. 5.



Showing (1) a flattened-out shrapnel ball embedded in the hamstring muscles; and (2) one lying in the medullary cavity of the femur.

At the operation the femur was exposed by an incision on the antero-external aspect of the thigh. The opening in the femur was readily found, but it was impossible to approach the ball by that route. Guided therefore by the rays a $\frac{3}{4}$-inch trephine was placed on the bone immediately over the foreign body and a circle of bone removed. The ball was extracted with a pair of sinus forceps through an opening which just accommodated it. The flattened-out ball lying among the hamstring muscles was removed *viâ* a short posterior incision. Up to the present (the fifth day) the patient's progress has been satisfactory in every respect.

The outstanding feature of the method is surely its simplicity. As a rule, the radiographer knows little about surgery and the surgeon less about radiography, but the profound knowledge of this is not an essential to the successful performance of projectile extraction.

In conclusion, it is gratifying to know that the method is attracting the attention it deserves. Those competent to pass an opinion who have seen foreign bodies extracted here have nothing but praise for a method so speedy and so successful. Adverse criticism comes only from those who have neither seen nor practised, and who are thus scarcely competent to judge.

Hôpital Sophie Berthelot, Calais.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A NOTE ON A MODIFIED FORM OF COLPO-PERINEORRHAPHY.

BY JAMES OLIVER, M.D. EDIN., F.R.S.E.

A PATIENT, aged 42, came under my care recently complaining of protrusion of the womb from the front passage and of the lower bowel. The protrusion of the womb had been in existence for nearly 20 years, and when I saw her the replacement of the uterus and vaginal walls was effected with some difficulty. The vaginal orifice was naturally very much relaxed. I performed on her a modified colpo-perineorrhaphy, and when the wound was quite healed the patient had a ring pessary placed, and thereafter neither the uterus nor the bowel caused her any inconvenience, and she was able to walk about in perfect comfort.

To most patients the retention of the prolapsed uterus and vaginal walls by means of a Zwanke pessary, or a pessary which has to be supported by a band encircling the abdomen, is irksome and inconvenient, and an operation which enables them to wear a watch-spring ring pessary with greater success and comfort is a decided boon. The modified colpo-perineorrhaphy, which I have found useful under such circumstances, consists in splitting the recto-vaginal septum close to the posterior margin of the vagina by means of perineal sharp-pointed scissors. The point of the dependent blade of the scissors is inserted close to the extreme left margin of the vaginal orifice and carried transversely under the skin to the extreme right margin. The same point of the scissors is then inserted under the skin at the extreme left margin of this transverse incision and carried upwards and slightly outwards for an inch or more, dividing the skin at the same time. A similar severance of the skin is effected on the right side, and an anterior or vaginal flap is thereupon dissected up to an extent varying with the requirements of each individual case, the left and right corners of this flap being held forward at the time by two pairs of pressure forceps. This flap is then divided centrally and vertically down to the rectum by the scissors. From the inner side of each of these vertically divided flaps a triangular piece is removed by snipping with scissors from the centre of the rectum upwards and outwards to the anterior limit of the two vertical and lateral incisions.

With a knife an incision skin-deep is then made posteriorly from the left margin of the original transverse incision to a spot close to and about the middle of the anterior portion of the sphincter ani muscle. A similar skin-deep incision is made on the right side and the V-shaped piece of skin thus outlined is dissected off. The raw surfaces thus created are then stitched in three layers, and as the greater portion of the sutures are buried I prefer to use 40-day No. 1 and No. 3 Van Horn catgut for stitching up. A curved needle carrying a short length of No. 1 catgut is inserted at the anterior limit of the incision on the left side avoiding inclusion of the skin and the mucous membrane, and the same armed needle is carried and made to traverse in a similar manner the anterior limit of the incision on the right side. This suture is then tied and left long, and held forward by a pair of pressure forceps. This act brings the raw mucous membrane edges of the vaginal flaps together centrally, and without transfixing the vaginal surface of these flaps the central cleft is closed by a continuous No. 1 catgut suture, beginning at the rectum and extending forward. By means of a continuous buried suture of No. 3 catgut, beginning posteriorly close to the sphincter ani and extending forward, the deep portion of the wound is now brought together, and thereafter the skin—beginning posteriorly—and the entire wound closed by a continuous No. 1 catgut suture, and just before tying this suture the catgut suture originally inserted at the anterior limit of the wound is cut short.

In some cases the need for a ring pessary is obviated by combining amputation of the cervix uteri with the aforesaid operation.

Harley-street, W.

A CASE OF PAROXYSMAL HÆMOGLOBINURIA.

By HAROLD E. THORN, M.R.C.S., L.R.C.P.LOND.,
SURGEON, R.N.

A. B., aged 18, in H.M.S. *Britannia*, came under observation on March 22nd complaining that seven days previously his urine had suddenly become very dark in colour. This lasted for three days and was succeeded by an interval in which he passed urine of normal colour. The same deep tint, however, returned, and he noticed it for two days previously to reporting himself. Whilst each of these attacks lasted there was pain in the lumbar region on both sides. On the evening of March 22nd the temperature was 99° F., but on every other day when under observation it was normal.

On examination the patient appeared very healthy. The urine was found to be dark in colour with a dirty deposit, which did not show any definite formation under the microscope. No blood cells could be seen. The reaction was acid and the specific gravity 1032. There was a large amount of albumin present, but no albuminometer was available for its definite estimation. The guaiacum blood test was strongly positive.

The patient was put to bed and the next day he had some lumbar pain, but the temperature was normal. The urine was just pink and there was only a trace of albumin. The reaction was still acid; specific gravity 1033. Two white blood corpuscles, but no red cells, were found in the deposit. Tubercle bacilli were not found. The back did not show any abnormal physical signs. The heart and lungs were normal. The systolic blood pressure was 120 mm. of mercury. The fundus oculi was also normal. Poikilocytosis was found and diminished rouleau formation in a blood film. There was no œdema of the limbs or back. On March 24th the urine had returned to normal and the patient was allowed to get up. Until that day he had been on light diet, but he was then allowed ordinary food, with the exception of rhubarb. Two days later (March 26th) the lumbar pain had disappeared. He was sent back to duty. Since then he has had two similar attacks, but was not seen by a medical officer owing to the fact that he went on leave for two weeks. He says that the third attack started on April 1st after a long walk, and that the fourth attack followed similar exercise within the next fortnight. He has now been quite well for eight weeks.

The patient is fond of taking cold baths, but these have been forbidden him. The attacks of paroxysmal hæmoglobinuria seem to follow exercise in every case, but a definite cause cannot be found. The remarkable thing about the case is the large amount of albumin which was present in the urine on the first day on which the patient came under observation and the rapidity with which it disappeared.

Medical Societies.

ROENTGEN SOCIETY.

X Ray Localisation Methods.—Discussion on Methods of Protection of X Ray Operators.

THE annual general meeting of this society was held on June 1st at the Cancer Hospital, Fulham-road, Sir **ALFRED PEARCE GOULD** being in the chair.

Captain J. H. **SHAXBY**, R.A.M.C. (T.), read a paper on X Ray Localisation Methods. He described two methods which had proved very serviceable in determining the position of foreign bodies, the first in certain special cases, the second for general work. It was sometimes impossible, he said, from a determination of the depth alone of a foreign body, to decide whether it lay above or below a broad flat bone such as the scapula. The remedy was to take two photographs from widely different angles of view, and the present method aimed at securing this in the two plates of the localisation. Briefly, it differed from the usual methods in two respects: (1) the anticathode, instead of being more or less in the vertical line through the foreign body, was placed markedly to one side, so that the views were both oblique; and (2) the displacement of the bulb between the two exposures was in a line perpendicular to the photographic plate, instead of parallel to it. As a result there was a considerably greater displacement of the shadow of the foreign body relatively to the adjacent bone than was given by the ordinary process. A simple formula, involving the distances of the two shadows from the point on the plates vertically over the focus spot, gave the position of the foreign body, or a thread method similar to Sir J. Mackenzie Davidson's might be employed. The second photographic plate might be raised equally with the bulb, keeping the distances of the plates apart fixed, or it might be placed in the same position as the first plate. The point alluded to, exactly above the focus spot, was determined by a fuse-wire grid in a fixed position over the anticathode; superposition of the plates and examination of the unequal-sized shadows of the wires made it possible accurately to find the required point. With apparatus which permitted of ready raising and lowering of the bulb the method was quick and simple, and the displacement of shadows large and correspondingly easy to measure accurately. For ordinary cases the usual procedure of moving the bulb parallel to the plate was followed, but the addition of a small auxiliary apparatus did away with the need for measuring the distance the bulb moved and also the distance from its focus spot to the negative. The appliance consisted of a small frame set up perpendicularly to the photographic plate and made of material transparent to X rays; this supported a series of parallel lead wires, arranged very much like the laths of a "Venetian" blind let down a little crookedly (Messrs. Newton and Wright, Wigmore-street, were the makers). The apparatus was mounted so that it could be easily clipped on to a plate envelope or casette, one end of the first wire being as close as possible to the plate. The slope of the wires was such that the other end of this wire was 1 cm. from the plate holder; the second wire, parallel to the first, lay 1 cm. from the plate at one end and therefore 2 cm. from it at the other. The distance of the third wire ranged in the same way from 2 to 3 cm., and so on for any convenient number of wires. The negative after the two exposures of the localisation showed two shadows of the foreign body and also two shadows of the lead wires. With a pair of divider compasses the displacement of the bullet shadows was set off, and the compasses were then moved to the wire shadows. If it was found, for instance, that a point a quarter of the way along one shadow of the fourth wire was at the set-off distance from the other shadow of the same point, then, very obviously, the bullet was at the same distance from the plate as this determined point on the wire system—a distance, that is, of 3·25 cm. The only care required in affixing the appliance to the plate was to put it so that the two shadows fell on opposite sides of its base, so that they did not overlap and give a confused pattern. For intensifying screen work or long exposures it was not advisable to expose the localiser throughout, or the density would become too great for convenient examination; the part of the plate where the wire shadows were to fall might be covered by a metal screen during the greater part of the process, the localiser being slipped into place only for the end of the first exposure and the beginning of the second.

Mr. SIDNEY RUSS, D.Sc., in opening a discussion on Methods of Protection of X ray Operators, drew attention to the special dangers attending X ray screen examinations. Efforts were made to protect the operator by enclosing the X ray bulb in a box covered with absorptive material, except in the path of the vertical rays used; the fluorescent screen over which the operator leant in order to interpret the image there presented was backed by lead glass to protect the face of the operator; gloves were also provided for use when manipulations of the patient had to be made while irradiation was going on. He directed attention to the extent to which the rays were cut off by the devices at present employed. He had recently made some measurements upon the percentage of radiation transmitted through various samples of protective material, which were at present being used in the army X ray installations. Considering first of all the bulb, it was usual for this to be enclosed in a wooden box lined within or covered by lead rubber or lead itself. There was no uniformity in the thickness or quality of lead rubber employed, with the result that the percentage of stray radiation was in some cases as low as 0·1 per cent., and in others as high as 5 per cent., of that of the primary beam of rays. With regard to the protective lead glass used in the fluorescent screens, the degree to which the rays were absorbed was found to depend very much upon the quality of the glass. A small increase in the amount of lead contained in the glass made a very large difference in its absorbing power, so that the quality of the glass in this respect was an important consideration. It was found by measurement that with the thickness of glass frequently in use at present as much as 4 per cent. of the energy of the beam reaching the fluorescent screen was received by the operator. What, then, were reasonable limits of safety in this respect? Dr. Russ thought it difficult for those engaged in X ray work to realise the enormous amount of radiation given out by modern bulbs; this was partly because the methods in use for the measurement of X rays were relatively gross methods. When an instrument such as an electroscope, which was a very delicate detector of X rays, was moved about in the neighbourhood of an X ray bulb which was accorded a reasonable amount of protection, it was astonishing to find what an amount of stray radiation there still was. It should be remembered that whenever this stray radiation was present the air became highly ionised, and upon this the ordinary methods of ventilation had no effect. It did not seem unreasonable to hope that in the not too distant future due attention would be paid to the atmosphere in which the radiologist conducted his examinations.

Dr. N. S. FINZI referred to the enormous output by the modern X ray bulb, not only of primary but also of secondary radiations. This was shown by an interesting experiment. If a tube were placed in a protective box that completely enclosed it except for the opening guarded by the diaphragm, very little secondary or other radiation was observable so long as the diaphragm was quite closed, but the moment the latter was opened, though only a very little, a strong secondary radiation could be detected anywhere in the immediate neighbourhood of the tube. This showed that while the usual protective box cut off nearly all the primary radiations there were the secondary rays to be considered which might be a great danger to the radiologist.

Mr. J. H. GARDINER, F.C.S., gave the results of experiments to determine the quality of the secondary radiations given off by various materials. Some surprising results were secured; for instance, paraffin wax gave off a more penetrating radiation than copper or silver. To him it seemed that any method of protection to be efficient must take account of the secondary radiations.

Dr. G. B. BATTEN considered this matter of X ray protection as one of the first importance at the present time when so many radiologists were working many hours every day in the military hospitals, and one of the greatest dangers was that in the absence of any definite rules it was more than likely that the protective measures in many of the X ray outfits supplied to the War Office fell short of what was desirable. He considered that a committee of the Roentgen Society should formulate a set of rules for X ray protection which would be a guide to makers and users of X ray apparatus.[1]

At the close of the meeting Dr. W. IRONSIDE BRUCE gave a demonstration of his method of accurately finding a foreign body in the tissues after it has been localised by the X rays. The apparatus was described in THE LANCET of Feb. 6th, 1915, p. 275.

LONDON DERMATOLOGICAL SOCIETY.—The annual general meeting of this society was held on June 15th at St. John's Hospital for Diseases of the Skin. Dr. W. Griffith, the President, presented the council's annual report. The balance sheet, which was presented by Dr. W. Knowsley Sibley, the honorary treasurer, was received and adopted. The following officers were elected for the ensuing year:—President: Dr. J. L. Bunch. Vice-Presidents: Dr. Morgan Dockrell and Dr. W. Griffith. Honorary treasurer: Dr. W. Knowsley Sibley. Honorary secretary: Dr. Simonds Gooding. Council: Dr. M. K. Hargreaves, Dr. R. Prosser White (Wigan), Mr. A. T. Bremner (Leicester), Mr. C. R. Kempster, Mr. C. H. Mills, and Mr. E. G. Reeve.—At the clinical meeting which followed a series of interesting cases were exhibited. Dr. Morgan Dockrell showed a case of Pityriasis Rubra Pilaris, and demonstrated the histological sections.– Major E. G. Ffrench, R.A.M.C., read a paper entitled "The Substitutes for Salvarsan and Neosalvarsan." He said that according to a report in THE LANCET of April 10th, 1915, by the secretary of the National Medical Research Committee, the chemistry of kharsivan and neokharsivan was said to be identical with salvarsan and neosalvarsan, the details of their preparation being identical. He said that he did not propose to discuss the chemistry of the preparation of these products, but rather to confine himself to observations made and the clinical results obtained after their use. He also mentioned a third substitute—viz., novarsenobenzol "billon," which was a French preparation manufactured by Poulenc Frères. Billon, he said, was a darker yellow colour than neosalvarsan, a yellow powder somewhat darker than the 914, dissolving readily in water and forming a clear yellow solution. For use it was dissolved in 10 c.c. of freshly distilled water and injected intravenously immediately afterwards. Neosalvarsan formed a clear yellow solution and dissolved readily. He first saw this concentrated solution tried with success by Professor John Fordyce, of the City Hospital, New York, in 1913, and since then he had adopted the method. Neokharsivan was a reddish-brown powder and dissolved quickly, forming a reddish-brown solution. Kharsivan was a yellow powder which did not dissolve readily in water. He recommended the following procedure. The powder was poured on to three dozen glass beads in a large sterile glass flask, the latter being shaken to allow the powder to mix with the beads; 20 c.c. of saline made of freshly distilled water was then added and the flask shaken with a swirling motion for a few seconds; more saline was then added and the flask shaken for about half a minute; finally the remaining portion of the 100 c.c. of saline was added and the flask was shaken again but not too vigorously. A clear yellow solution was the result, and the time taken was about three minutes. The solution was then neutralised with a 4 per cent. solution of sodium hydrate, the quantity required to dissolve the 0·6 grm. being 4·8 c.c. After neutralising another 150 c.c. of saline was added, making the total amount 250 c.c. The strength of the salt solution used was 0·9 per cent.—that is, 8·5 grm. of sodium chloride to 1 litre of distilled water. It was injected at body temperature. With regard to neosalvarsan, neokharsivan, and billon, the same amount of water, 10 c.c., was used to dissolve a moderate or full dose, the solution being injected cold owing to the greater tendency to rapid oxidation. The method of injection was as follows. A 10 c.c. record syringe was used; the barrel was filled and the needle introduced into the vein, the piston being withdrawn slightly so as to see if the needle had entered the lumen of the vessel. If it had, the piston might be gradually pushed home. The skin over the vein was painted with a solution of iodine and chloroform, 1/15, before and after the operation, and a piece of sterile gauze was placed over the puncture and sealed with collodion. The day before injection all the organs and urine of the patient were examined, and pil. hydrarg., gr. 4, given in the evening and mist. alba, 1 oz., in the morning. At 7.30 A.M. breakfast, consisting of tea and bread-and-butter, was allowed, and the injection was given in the forenoon. If there were no immediate after-effects the patient was given tea and bread-and-butter at 4.30 P.M. Ordinary hospital dinner was allowed at 7.30 P.M. if the patient still remained free from temperature, vomiting, headaches, &c. He was kept in bed until the following morning. The routine method of dosage was to give three intravenous injections of salvarsan or neosalvarsan at intervals of ten days. The day after the first injection mercurial cream, grm. 1, was injected into the buttock and carried out for nine consecutive weeks. 0·6 grm. salvarsan or 0·9 grm. neosalvarsan was nearly always given as the first dose; 0·4 grm. salvarsan or 0·6 grm. neosalvarsan was given as a second dose unless the patient had only a moderate dose at first, when a full dose was given. A full dose was given for the third injection. The same procedure was being adopted with the substitutes kharsivan, neokharsivan, and novarsenobenzol. Major Ffrench said that over a hundred cases, comprising primary, secondary, and tertiary, had now been treated with the substitutes, and that they had come to the conclusion that kharsivan and neokharsivan were somewhat more toxic than salvarsan and neosalvarsan. He gave the following percentages of immediate after-effects produced. Of 136 injections of kharsivan 60 per cent. gave no reaction; 27 per cent. gave slight reaction, such [illegible] headache, slight temperature, vomiting, rigor, and diarrhœa; and 13 per cent. gave severe reaction of the symptoms mentioned. Of the 124 injections of salvarsan, 63 per cent. gave no reaction, 33 per cent. slight reaction, and only 4 per cent. severe. Of the salvarsan cases, 20 per cent. were primary, 75 per cent. secondary, and 5 per cent. tertiary. Of the 25 injections of neokharsivan, 32 per cent. gave no reaction, 40 per cent. slight reaction, and 28 per cent. severe; 20 per cent. were primary, 48 per cent. were secondary, and 32 per cent. were tertiary. Compared to neosalvarsan, of the 75 injections 72 per cent. gave no reaction, 21 per cent. slight, and only 7 per cent. severe. The primary were 40 per cent., secondary 26 per cent., and tertiary 34 per cent. Of novarsenobenzol, 42 injections were given; 76 per cent. gave no reaction, 19 per cent. slight reaction, and 5 per cent. severe. There were 12·5 per cent. primary, 12·5 per cent. secondary, and 75 per cent. tertiary. The greatest number of severe reactions occurred in the secondary and late primary cases. He said that it was most satisfactory to state that they had not experienced any serious results in the use of these substitutes, and that they believed that kharsivan and neokharsivan were very excellent substitutes (for salvarsan and neosalvarsan), and that so far as their experience had gone they might be safely recommended for the treatment of all forms of syphilis.

---

[1] This suggestion was adopted and the council of the Roentgen Society have undertaken to give effect to it.

Reviews and Notices of Books.

Heredity and Environment in the Development of Man.

By EDWIN GRANT CONKLIN, Professor of Biology in Princeton University. London: Humphrey Milford. 1915. Pp. 533. Price 8*s.* 6*d.* net.

THIS interesting volume on an ever-expanding subject is composed of the Norman Wait Harris Lectures for 1914, which were given at Northwestern University and subsequently repeated at Princeton University. The lectures were founded in 1906 through the generosity of N. W. Harris, of Chicago, and are to be given annually. Such diverse subjects as personalism, university administration, the age of mammals, democracy and poetry, the milk question, and the constitution of matter have already been dealt with by previous lecturers. The purpose of the lectures is "to stimulate scientific research of the highest type and to bring the results of such research before the students and friends of Northwestern University, and through them before the world. By the term 'scientific research' is meant scholarly investigation into any department of human thought or effort without limitation to research in the so-called natural sciences, but with a desire that such investigation should be extended to cover the whole field of human knowledge."

The text consists of six chapters or lectures, illustrated by nearly 100 figures. The subjects dealt with are: (1) Facts and Factors of Development; (2) Cellular Basis of Heredity and Development; (3) Phenomena of Inheritance; (4) Influence of Environment; (5) Control of Heredity, Eugenics; (6) Genetics and Ethics.

As a result of the doctrine of organic evolution it has become plain that man's place in nature has been clearly defined, and the resemblance between men and the lower animals has come to have a new significance. It is recognised that life processes are everywhere the same in principle, though varying greatly in detail, so that all the general laws which apply to animals and plants apply to man. It is on this foundation that the recent wonderful advances in experimental medicine have become possible.

If the origin of species was the greatest biological problem of the past century, assuredly the origin of individuals is the greatest biological subject of the present one. This is the author's theme. He deals first with the phenomena of development, including such trite subjects as the germ cells, fertilisation, cleavage, embryogeny, organogeny, oviparity and viviparity, and development of functions. He shows that every living being is a complex system in dynamic equilibrium and manifests the following features. It contains protoplasm, and its equilibrium is maintained by the physiological processes known as metabolism, reproduction, and irritability. The development of functions goes hand in hand with the development of structures; indeed, "function and structure are merely different aspects of one and the same thing —namely, organisation." As to the origin of the mind, or rather of the soul, "the only possible scientific position is that the mind (or soul) as well as the body develops from the germ....... The mind develops by gradual and natural processes from a simple condition which can scarcely be called mind at all."

Further, says the author, there is no more reason for supposing that the mind is supernaturally created than that the body is, the mind being related to the body as function is to structure. The development of the mind is treated under the following heads: (*a*) Sensitivity; (*b*) tropisms, reflexes, instincts; (*c*) memory; (*d*) intellect, reason; (*e*) will; (*f*) consciousness. The first lecture is brought to a close by a short chapter on factors of development, including an account of the doctrines of preformation and epigenesis. The author's teaching may be thus summarised: The intrinsic factors of development reside in the organisation of the germ cells; the extrinsic are represented in environmental forces and conditions; the intrinsic factors are commonly called heredity; they in the main direct and guide development, while the environmental factors furnish the conditions in which development takes place and modify, more or less, its course.

In discussing the cellular basis of heredity and development the author's position is that all the phenomena of life, including heredity and development, are cellular phenomena in that they include only the activities of cells or of cell aggregates. Heredity originally meant "heirship or transmission of property from parents to children." In the field of biology it has been defined erroneously, says the author, as "the transmission of qualities or characteristics, mental and physical, from parents to offspring." We are told roundly that no "qualities" or "characteristics" are "transmitted" as such from one generation to the next. The following is the author's definition and summary: "Heredity may be defined as the appearance in offspring of characters whose differential causes are found in the germ cells. Heritage is the sum of all those qualities which are determined or caused by this germinal organisation. Development is progressive and coördinated differentiation of this germinal organisation, by which it is transformed into the adult organisation. Differentiation is the formation and localisation of many different kinds of substances out of the germinal substance, of many different structures and functions out of the relatively simple structures and functions of the oosperm." The germ is thus the undeveloped organism which forms the bond between successive generations; the person is the developed organism under the influence of environmental conditions—"the person is merely the carrier of the germ plasm, the mortal trustee of an immortal substance."

An elaborate account of germ cells is given, and the significance of the successive events is discussed under the headings fertilisation, cleavage and differentiation, origin of the sex cells, and sex determination. The author asserts that sex is irrevocably determined at the time of fertilisation. As to the mechanism of heredity, as contrasted with the mechanism of development, it consists in the formation of particular kinds of germ cells and in the union of certain of these cells in fertilisation. Germ cells have a certain "specificity." Germ cells of different individuals are not all alike, and such differences are due to one or more differentiating causes or factors—intrinsic or extrinsic—though experience has shown that they are generally intrinsic in the germ. The author shows that in woman, where "there are probably 48 chromosomes and after synapsis 24 pairs of maternal and paternal ones, the possible number of permutations in the distribution of these chromosomes to the different egg cells would be 2^{24}, or 16,777,036, and the possible number of different types of fertilised eggs or oosperms which could be produced by a single pair of parents would be $(16{,}777{,}036)^2$, or approximately three hundred thousand billions." It would seem as though the production of unique individuals were the chief purpose and result of sexual reproduction. That the chromosomes play a large and dominant rôle is admitted, and the author compares their behaviour in maturation and fertilisation to the shuffle and deal of cards in a game and apparently with the same object—viz., never to have the same distribution twice. A careful exposition is given of the reasons for assuming that the chromosomes are important factors in heredity and differentiation.

As to the phenomena of inheritance, the author says that "like does not produce like but only somewhat like." Hereditary resemblances are first dealt with, including racial characters and individual characters. Under the latter heading we find interesting references to morphological features, teratological, pathological, and physiological peculiarities, and psychological characters. To Francis Galton is due the credit of being one of the first to bring order out of chaos by dealing singly with traits or characters instead of treating all together. "Mutations" and "fluctuations" are dealt with, and in the end the conclusion is arrived at that every individual is unique—every living being apparently is the first and last of his identical kind. The whole chapter on Mendelism is excellent and worthy of the most careful study as a sound, terse, and luminous exposition of this very practical doctrine; indeed, the author regards "the principles of heredity as established by Mendel as almost as important for biology as the atomic theory of Dalton is for chemistry."

The influence of environment on heredity, or, in the words of Galton, the two sets of factors, "nature" and "nurture," are considered fully, and the author finds that developed characters, whether "acquired" or not, are never transmitted by heredity, the hereditary constitution of the germ not being changed by changes in such characters. It is possible to guide phenomena of heredity and evolution. Accepting this statement, the author gives in the fifth chapter an interesting account of the "control" of heredity and of eugenics, dealing with such well-known subjects as the influence of environment in producing new races, artificial selection, methods of modern genetics, and control of human heredity. The last chapter, on genetics and ethics, or at least a portion of it, was published in 1913 under the title "Heredity and Responsibility."

We have great pleasure in commending the study of these instructive and suggestive lectures to all who are interested in the problems of heredity and environment as they affect the development of animals and man. Much old ground is necessarily traversed, but the comprehensive way in which the subjects are treated makes these repetitions illuminating.

The Chemistry of Colloids.

By W. W. TAYLOR, M.A., D.Sc. London: Edward Arnold. 1915. Pp. 328. Price 7*s.* 6*d.* net.

THE study of the chemistry of colloids grows in importance day by day, and it seems strange that until quite recent years very little progress has been made since Graham's experiments in the early "sixties." But the recent progress made has been very real, so much so that the chemistry of colloids has now many applications in the industries. After a very clear account in general of the colloids, and a sketch of the researches which have led up to the present position of the study, Dr. Taylor reserves four chapters to their applications. Thus, amongst the semi-colloids are included casein and the soaps. He then proceeds to the modern dyes, discussing their colloid nature, the mutual precipitation of the colloid dyes by other colloids, mordants, lakes, and so forth. Then follows a chapter on tanning, the soil and its purification, in which colloidal processes are undoubtedly concerned, if only in a mysterious way. Lastly, a very interesting chapter is the final one on the applications of colloid chemistry to physiology and biology, as evidenced in the rôle of hæmoglobin in the blood, the action of enzymes, the phenomena of catalysis, and agglutination. All these questions claim attention from the point of view of colloidal chemistry, and this book will be cordially welcomed as the first English text-book on the subject, and as one that sets up an admirable model for others to work upon who, as researches develop, may be tempted to expand the subject.

A Text-book of Insanity and Other Mental Disorders. By C. A. MERCIER, M.D. Lond., F.R.C.P. Lond., F.R.C.S. Eng. Second edition. London: George Allen and Unwin, Limited. Price 7*s.* 6*d.*

WE remember Dr. Mercier to have defined science as order, system, organisation, arrangement —in short, as the recognition and application of law. His text-book was designed to make our knowledge of insanity in this sense scientific and to arrange the subject in accordance with an orderly system. The second edition which has now appeared carries the attempt farther, and aims to provide a systematic arrangement of the whole subject and of its several parts; and though Dr. Mercier's may not be the best arrangement, it is at any rate an orderly and systematic one pursued with considerable detail.

The first requisite for the study of a subject is to have a clear notion of the subject to be studied, and from the beginning we can see what Dr. Mercier would be at. Considering that it has hitherto been a general assumption, both in medicine and in law, that insanity is disorder of mind (an assumption which is widely held and is embodied in Acts of Parliament), the author strenuously contends that insanity has in common use several meanings which are not distinguished, and that in every one of these meanings the most important ingredient is disorder, not of mind, but of conduct. The argument is that what matters is not what a patient believes or thinks, but what he says and does. It is disorder of conduct on which the main emphasis is laid, and certain of its results are discussed and described in a way and with a fulness constituting, if memory serves us, new features in a book on insanity.

Disorder of mind is, however, an ingredient or constituent of insanity, and we agree with Dr. Mercier that the study of insanity should be preceded by a study of normal psychology. Experience appears to have convinced him that the study of the normal mind and the explanation of the constitution of the normal mind, as given in the text-books of psychology, do not serve the purposes of the student of insanity, and he formulates a new scheme of the constitution of mind specially adapted to the needs of the student of insanity. The scheme may be right or wrong, but among the causes of insanity usually recognised there are too many disconnected surmises, and Dr. Mercier's plan finds a place for those processes of mind whose disorders come under the notice of the physician. The causes of insanity are here reduced to two complementary and relative sets—heredity and stress—each of which is systematically treated, the manner in which they act as causes is suggested, and the stresses are arranged in a systematic manner. Classification is Dr. Mercier's aim here, and no classification of the causes of insanity hitherto proposed has been satisfactory. Dr. Mercier asserts that confusion and cross-classification arise from the failure to distinguish between the various meanings of the word insanity, which may mean a disease or may mean a symptom, and that when these meanings are disentangled, when symptoms are classified by themselves, diseases by themselves, and acute and chronic conditions by themselves, the difficulties of classification will be surmounted. Dr. Mercier suggests three valid arrangements free from cross-classification in substitution for a single arrangement in which the three are blended, but we are not certain that he will wholly escape the reproach of cross-classification. Confusion, too, may be introduced in one or two places by the use of terms with an unusual significance, or at any rate with a significance that is not generally accepted. In the course of the book some clinical types of insanity, hitherto, we believe, unrecognised, are described for the first time.

The book suffers from compression. The author tries to say too much in too small a space. He allows his criticism of his colleagues for acquiescence in the claims of the German school to become too apparent. He is impatient, because he has found it impossible to obtain recognition for the importance of disorder of conduct in relation to insanity, insanity being usually treated as disorder of mind even when psychology is seen to be at fault. He is sore because his views, which amount to a revolution in the concept of insanity and in the treatment of the subject, remain undiscussed. The book appears to have been written in an angry mood from title to index, as if the author were at enmity with every other writer on the subject, and the warning to examinees not to read the whole lest they should know more than their examiners is droll but very aggressive. Instead of an index, we find an argument why this should be missing. The gibe at the reviewers that the absence of an index will hamper their work has some point, for many books are in these days of gross over-production noticed in a perfunctory manner by critics whose knowledge of the contents is much derived from the "contents page." But when Dr. Mercier writes "To add an index to a book that is logically arranged is to take for granted that the reader is not intelligent enough to appreciate a logical argument," does he see that he may demand from his reviewer the perusal of the whole of his work? The author of a book is not necessarily the best judge of whether it is logically arranged, and no arrangement can necessarily be exactly the best one. A reviewer might look for a sequence of ideas which would seem logical to him, might find that sequence broken and conclude that some points were missing, when, in accordance with the author's view of logic, those points were considered elsewhere. In the absence of an index how is the reviewer to be assisted? Dr. Mercier is surely too reasonable to say "let him read the whole book and read it steadily and carefully," for that is an unfair demand on a reviewer: a man does not drink a bottle of wine steadily and carefully before saying if it is a sound and palatable fluid.

This is a pugnacious, dogmatic, and very clever book, and the general practitioner will certainly obtain from it valuable lessons as to his conception of insanity. It is readable from first to last.

The Diseases of Children.

Edited by Dr. M. Pfaundler, Munich, and Dr. A. Schlossmann, Düsseldorf. English translation edited by Henry L. K. Shaw, M.D., Albany, N.Y., and L. La Fétra, M.D., New York. Vol. VII. *Diseases of the Eye in Infancy and Childhood.* By Dr. Oskar Eversbusch, Munich. *Disorders of Speech and Phonation.* By Dr. Max Nadoleczny, Munich. London and Philadelphia: J. B. Lippincott Company. 1915. Pp. 499. Price 21*s.* net.

In the seventh volume of Pfaundler and Schlossmann's "Diseases of Children," translated by Dr. Shaw and Dr. La Fétra, the treatise on the Diseases of the Eye in Children, written by the late Dr. Eversbusch of Munich, is probably the most exhaustive which has appeared. It necessarily contains little which is not to be found in any of the larger text-books of ophthalmology, but it segregates the diseases which are found in children and thus serves a good purpose in emphasising this particular aspect of the subject. Whether the task was quite worth doing in this elaborate fashion is a matter of opinion, but at any rate it has been done well. The first chapter deals with congenital anomalies and deformities of the eye. It is a fairly complete account. Here and elsewhere authors are mentioned, but no references are given. The second chapter, entitled the "Development of the Infantile Eye," really deals with the anatomy of the eye in the child, and contains much information otherwise difficult of access and little known. The examination of children with ocular affections is treated rather scantily, a knowledge of the ordinary methods of examination being presumed. Then follow chapters on diseases of the eye and adnexa, arranged after the usual fashion of ophthalmic text-books. There is a special chapter on disturbances of pupillary movements. The discussion of the diseases is essentially clinical, very little reference being made to pathology. Treatment is very fully dealt with.

The second part of the volume is taken up with the consideration of a comparatively small but none the less important section of the diseases of children—viz., disturbances in the realm of speech. After a preliminary chapter on the development of the faculty of speech, viewed both physiologically and psychologically, the author proceeds to investigate its disorders by dividing them into two main groups—arrests of development of speech and disorders contracted after speech is acquired. In the former category are placed three subclasses—viz.: 1. Arrests of development on the peripheral sensory side, such, for instance, as total or partial deafness, with or without total or partial blindness. 2. Arrests of development of central sensory origin, including word-deafness, word-dumbness, voluntary whispering, agrammatismus and akataphasia (inability to form sentences syntactically correct), and various forms of stammering. The author defines the last of these as "inability of uttering or correctly forming certain sounds or sound combinations," hence there may be vowel-stammering, stammering in labial sounds, in dental, palatal sounds, L- and R-stammering, &c. 3. Arrests of development in the peripheral expressive mechanism, including lisping in its various forms, and snuffling. The second main group is concerned with disorders arising after speech is acquired, such as stuttering, which is defined as "a spastic neurosis of cöordination interfering ...... with the pronunciation of initial syllables or of words in the middle of a sentence. The articulation of every sound is correct." In the same group are disorders of speech at puberty, those associated with various nervous diseases such as chorea, epilepsy, hysteria, and tic, also those that are found in cases of imbecility, and in organic conditions such as encephalitis, infantile cerebral paralysis, facial paralysis, disease of other peripheral nerves and muscles, and so on; mainly, therefore, a symptomatological group. There is a special subsection on the varieties of mutism.

We do not know any treatise in which the manifold disorders of speech in children are so minutely described and their treatment so carefully and practically demonstrated. If the practitioner has hitherto been too often content to assure the anxious parents that the child will "grow out of its defect" a perusal of this book will teach him the urgent necessity of painstaking diagnosis and of systematic treatment. The whole subject has been too much neglected by medical men, with the result that it has become the happy hunting ground of charlatans and quacks of every description. This division of the volume can be cordially recommended to the earnest attention of the inquiring general practitioner, as well as to the neurologist and psychologist. Further, those who are concerned with pedagogy and with phonology might read the book with profit, though we agree with the author in his contention that official medicine should take the subject up from henceforward, for the treatment of disorders of speech should be scientific, not empirical.

The work is excellently printed, though on unnecessarily heavy paper. There are 20 admirable coloured plates and numerous good illustrations.

LIBRARY TABLE.

The Vicious Circles of Neurasthenia and their Treatment. By Jamieson B. Hurry, M.A., M.D. Cantab. With illustrations. London: J. and A. Churchill. 1915. Pp. 90. Price 3*s.* 6*d.* net.—The establishment of vicious circles in disease is a familiar clinical fact. Dr. Hurry takes neurasthenia, and works out the action of the vicious circle in the different systems of the body affected in that disease. He exemplifies the mode of action in the case of the vascular, respiratory, digestive, and genito-urinary systems, as well as in the psychical sphere. A large number of quotations from other authors, in practically every one of which the words "vicious circle" occur, are adduced to "guard against any possible charge of obsession in reference to the rôle of the circle." The breaking of the circle by treatment is discussed along accepted lines. If there is little that is novel in the book, it furnishes good illustrations of the widespread influence of pathological inter-relations as displayed in the particular case of neurasthenia.

The Body in Health. By M. V. O'Shea and J. H. Kellogg. Illustrated. New York: The Macmillan Company. 1915. Pp. 324. Price 3*s.* 6*d.*—This little volume represents the latest addition to the

Health Series of Physiology and Hygiene, a series of popular works intended to present in an attractive form for pupils in the elementary schools accurate information on the hygiene of daily life. The book is freely illustrated by photographs and drawings in order that important matters relating to health may be impressed upon the eye of students. At the end of each chapter a number of problems are set on the subject matter dealt with in the text. It is intended that problems shall be worked out in the class-room and discussed freely between pupils and teachers. This method of engaging the interest and teaching the practical applications of a lesson has been found to bear excellent fruit in schools in America in which the system has been adopted. As an example of the problems set we give the following from the end of Chapter VI., which deals with the heart and blood: "Can you tell when you look at a person whether or not his blood is pure? Why should blood cells be kept in good fighting condition?" Both authors have the faculty of making common-place details attractive, and of investing even dry bones with picturesqueness. The special senses are described as gateways to the mind. The excretory functions are described in a chapter entitled "How the Body Cleanses Itself." The cells are called the little workers of the body and disease germs the enemies of the body. The authors are to be congratulated on their courage in essaying to explain some of the most difficult problems in physiology and pathology to the half-developed minds of children; it would in many cases have been simpler to have shirked these questions or to have circumvented them by subterfuges and inaccuracies. We sincerely hope that this little work will find its way into the hands of teachers in our own elementary and secondary schools.

Materia Medica and Pharmacy for Medical Students, with an Appendix on Incompatibility. By REGINALD R. BENNETT, B.Sc. Lond., F.I.C., Pharmacist and Teacher of Pharmacy to University College Hospital, London. Third edition. London: H. K. Lewis. 1915. Pp. 248. Price 4*s.* 6*d.* net.—The third edition of this useful and practical little work has been completely revised and brought into conformity with the new Pharmacopœia. The pharmacological classification of the previous editions, however, has been retained, and the apothecaries' system of dosage has been included in parentheses after the metric system, which is that now used in the Pharmacopœia.

A Hausa Phrase-Book, with Medical and Scientific Vocabularies. By ALLAN C. PARSONS, M.R.C.S., L.R.C.P. Lond., D.P.H. Oxon., Sanitary Officer, Gold Coast. Oxford University Press (Humphrey Milford). 1915. Pp. 164. Price 7*s.* 6*d.* net.—This book contains a series of phrases with Hausa translation, intended for those who wish to gain a speaking acquaintance with that language. It is divided into three parts: Part I., phrases in general use, consisting of miscellaneous idioms and phrases relating to household management, travelling, stable management, and hunting; Part II., departmental phrases, political and administrative, military and police, public works, forestry and agriculture, customs, commercial, mining, nursing, and hospital management and medical terms. Part III. contains English-Hausa and Hausa-English vocabularies of medical and scientific words. From the point of view of the would-be learner the chief criticism we would make is on the absence of any anatomical dissection of the language, in consequence of which the sentences seem to call for individual memorisation, throwing the same strain upon a retentive memory that is needed for mastering Chinese ideographs. It would be a huge task for the student wishing to make practical use of the book to turn up a sentence that would serve him to express the particular idea in his mind, whether assertion or question. In a book of this description we think the more scientific plan would be to build up progressive models of expression which could be varied with an increasing vocabulary by the mere change of one or two words. Another difficulty is that no scheme of phonetics is appended to enable the reader to estimate the correct pronunciation of the Hausa words. From the point of view of the printing, also, we think that it would have been much better to use different types for the English and the Hausa. The book, doubtless, will be of service to residents in the Hausa-speaking districts of the West Coast of Africa after they have already made some acquaintance with the language.

JOURNALS.

The British Dental Journal.—In the June issue of this journal there is a paper by Mr. E. D. Davis on the Pathology and Treatment of the Maxillary Antrum. The author considers that antral suppuration is but seldom traceable to dental causes, and when due to such causes he considers that the third molar is most commonly the offending tooth. Alveolar puncture, in his opinion, is highly unsatisfactory, and even when the cause is dental in origin he thinks that extraction of the tooth followed by syringing the antrum from the nose gives better results than irrigation through the tooth socket. Mr. Wesley Barritt has an interesting paper on Synthetic Drugs and Chemicals, and Mr. Claude Colyer a letter on Army Dentistry, in which he suggests some methods of treatment based upon his experience with the Expeditionary Force.

THE METROPOLITAN WATER-SUPPLY.

THE report on the condition of the Metropolitan water-supply during the month of February, 1915, was issued last week. The results are of more than usual interest owing to the fact that in the Thames basin the rainfall during February was 4·57 inches, which is 2·66 inches above the average mean rainfall for that month during the previous 32 years. The statement shows that the Thames water was in good condition from the 1st to the 3rd and from the 24th to the end of the month; on the remaining days, however, it was more or less coloured and turbid while the increased water was flowing. The samples of water collected at the different works were clear, bright, and free from suspended matter, showing that the storage and filtration systems adequately deal with the increased suspended matter and colouring in the raw water caused by a higher rainfall. In Dr. A. C. Houston's official report on the chemical and bacteriological examination of the water-supply there is an abundance of detail, and the numerous tables show what an enormous amount of laboratory work is done in this direction. Owing, however, to the heavy cost of publication the figures given in the report must be regarded, Dr. Houston states, as summaries and averages only of complete details. In regard to chemical examination, the *raw* Thames waters deteriorated and the Lee water also, except as regards albuminoid nitrogen, while the *raw* New River water improved. The three *raw* waters compared with the averages of

1914 yielded results worse than their respective averages as judged by the albuminoid nitrogen, permanganate, turbidity, and colour tests, while all the *filtered* waters yielded also worse results. In the bacteriological examination all three *raw* waters contained more bacteria than their respective averages in the previous year. The *filtered* waters, generally speaking, yielded not unsatisfactory results. It is shown that in February, 1915, whereas 100·0, 90·0, and 80·0 per cent. of the samples of *raw* Thames, Lee, and New River water respectively contained typical B. coli in 1 cubic centimetre (or less), 62·7, 80·0, and 59·4 per cent. of the *filtered* samples derived from these rivers contained no typical B. coli even in 100 times as much water—namely, 100 cubic centimetres. Even, therefore, under conditions of pressure when a greater demand is made upon the capacity of the purifying installations the water reaches the consumer in a bacteriologically safe condition. This speaks eloquently of the high efficiency of the methods of purification adopted, storage and filtration, and the scientific investigations made on these questions by Dr. Houston in the past may well entitle him to be proud of the satisfactory practical results to which that work has led.

Reports and Analytical Records

FROM

THE LANCET LABORATORY.

OXYDOL.

(NEW OXYDOL PRODUCTS, LIMITED, 23, FITZROY-SQUARE, LONDON, W.)

WE have examined two samples of peculiarly pure hydrogen peroxide sold under the name of oxydol. Both samples were bright, colourless, and non-acid. We made a careful search for the common impurities of hydrogen peroxide such as baryta and sulphuric acid and chlorine, but with negative results. One sample contained peroxide of hydrogen equal to three volumes of available oxygen and the other six volumes of oxygen. For medicinal purposes, of course, peroxide of hydrogen should show a high degree of purity. Oxydol is well adapted for antiseptic treatment, and it is necessary, particularly in the treatment of wounds, that no acid should be present, as this may cause irritation.

ENERGEN BREAD.

(THE THERAPEUTIC FOODS COMPANY, BEDFORD CHAMBERS, COVENT GARDEN, LONDON, W.C.)

Energen bread according to our analysis resembles the composition of ordinary bread with the important exception that a proportion of the starch has been eliminated and an addition of some fat has been made. It may be described, therefore, as a partial gluten bread, and its texture suggests this. According to our analysis the bread has the following composition: moisture, 7·20 per cent.; mineral matter, 0·60 per cent.; protein, 32·19 per cent.; carbohydrate, 52·60 per cent.; fat, 5·44 per cent.; and fibre, 1·97 per cent. The bread is palatable and provides a suitable food in those cases in which some tolerance for carbohydrates is exhibited. There seems little doubt that the diabetic patient in some instances may take a regulated quantity of carbohydrate, but, of course, the allowance must be watched. Energen bread is useful for this purpose.

PIPERAZINE CITRATE.

(ALFRED BISHOP, LIMITED, 48, SPELMAN-STREET, LONDON, N.E.)

The introduction of piperazine in the form of citrate enables this base to be given in the shape of a non-hygroscopic and non-volatile salt. The preparation before us is well made and occurs in fine white granules. It is readily soluble in water, the solution having a saline and slightly bitter taste. It appears to be well established that piperazine or its salts do afford relief in gouty conditions. It has also been employed in neuritis and sciatica. Its mode of action does not appear to be quite clear, but it is generally stated to have a soluble action upon uric acid, piperazine urate being a much more soluble and diffusible salt than the ordinary alkaline urates. The citrate appears to be a very good form for exhibition in these cases.

TRI-MUR-TI.

(THE TRI-MUR-TI COMPANY, 11, HILLS-PLACE, OXFORD-STREET, LONDON, W.)

This is an opalescent, pearly-looking jelly containing a large proportion of pure solidified petroleum associated with oil of peppermint. It is primarily intended as a laxative, but, of course, the oil of peppermint contributes therapeutic properties, serving, as is well known, as an anti-spasmodic or carminative. By those who like the taste of peppermint, as children do, the preparation is well taken. On the whole it seems to be a useful combination, and it is well prepared, showing a perfectly uniform consistence. According to our analysis it contains 94 per cent. by weight of petroleum. This, of course, gives a higher figure by volume according to the density of the hydrocarbon oil used.

LYSOL ANTISEPTIC TOILET SOAP.

(MESSRS. CHAS. ZIMMERMANN AND CO. (CHEMICALS), LIMITED, 9 AND 10, ST. MARY-AT-HILL, LONDON, E.C.)

This is an agreeable toilet soap reinforced with 5 per cent. of the well-known antiseptic and detergent lysol. On decomposing the soap with acid and distilling, about 2½ per cent. of cresols was obtained. It very freely lathers, yielding a bulky foam, and leaving a marked sense of cleanliness. It shows an alkaline reaction to phenolphthalein, the presence of the alkaline lysol adding materially to the detergent properties of the soap. It is agreeably scented, and there is little evidence of the presence of lysol to the smell.

TWO AGREEABLE COCOAS.

(MESSRS. CADBURY BROS., BOURNVILLE, BIRMINGHAM.)

Cocoa is fulfilling an important rôle just now, inasmuch as its nutrient and mildly stimulating qualities are much appreciated by our soldiers, both those actively serving and the wounded. We have received from the above firm two samples of cocoa which upon making an analysis show certain differences in composition. Bournville cocoa (flavoured) gave the following results: moisture, 4·87 per cent.; mineral matter, 8·60 per cent.; fat, 26·55 per cent.; alkalinity of ash in terms of potash, 3·94 per cent. The unflavoured essence gave the following results: moisture, 3·30 per cent.; mineral matter, 5·05 per cent.; fat, 25·62 per cent.; alkalinity of ash in terms of potash, 0·70 per cent. Both are high-grade, attractively flavoured cocoas, the Bournville showing an increased "solubility" over the unflavoured specimen, due to the presence of a larger percentage of salts, as revealed in the analysis.

THE LANCET.

LONDON: SATURDAY, JUNE 26, 1915.

Midwives and Moral Character.

A RECENT decision of the High Court with reference to a midwife who had been struck off the official register by the Central Midwives Board was calculated to give the impression that the decision of the Board had been reversed upon appeal as to an important question of principle. This, however, we believe, is not the case. The matter was brought before the Central Midwives Board at a recent meeting, when a letter was considered which had been addressed to the Board by the honorary secretary of the Midwives' Institute. This letter referred to the fact that the charge upon which the Board had ordered the midwife's name to be removed from the Roll was one of immorality, and acknowledged that the reversal of the Board's decision was on account of a technical omission in connexion with the proceedings taken. It went on, however, to point out that the result of the case was likely to lay the decision of the judges open to very serious misconstruction in the mind of the general public. The secretary of the Midwives' Institute had therefore been instructed to forward to the Board a resolution passed by the Institute that "The Midwives' Institute respectfully asks the Central Midwives Board to make a pronouncement, which can be reported in the press, that in spite of the High Court's reversal of the Central Midwives Board's decision in a recent case, the Board will, as it has heretofore done, continue to support the moral as well as the professional status of practising midwives." The reply to this, which the Board resolved to make at the meeting referred to, is decisive and eminently satisfactory. It refers to the judgment of the court as having reversed the Board's decision with regard to the midwife in question, but describes it as having confirmed the Board in its position as the authority determining what is or is not misconduct in a midwife, and as having decided that misconduct is not to be limited to misconduct in a professional sense. The Board, further defining the principles upon which it is prepared to act in such matters, stated its opinion that conduct which before enrolment would render it impossible to certify that a candidate was of "good moral character" renders her, after enrolment, liable to be removed from the Roll for "misconduct"; and the Board declared that there was no likelihood that it would depart from this position.

The declaration thus made is, as we have said, eminently satisfactory. To have found that the Board had been compelled by legal decision to abandon all consideration of the moral character of a midwife after once admitting her to practice among the women who might seek her aid, would have been more than disconcerting. It would have been disastrous, and we can well understand the desire of the Midwives' Institute to obtain a pronouncement which, through the medium of the press, should do much to correct the wrong impression likely to be conveyed by the report of the appeal referred to. The practice of a midwife, implying attendance upon women and to treating them in, and in connexion with, pregnancy and childbirth, brings her in contact with females of the humbler classes of society, with married women of the strictest respectability, and with those in very different circumstances. It is difficult to imagine any person whose opportunity for mischief among her sex would be greater if she herself were to be of loose morals and at the same time endowed with the training and skill which the Midwives Act, 1902, was passed to promote. The Act itself clearly states the intention of those who framed it, for in Section 2, where it provided for the immediate admission to the roll of persons having certain stated professional qualifications, it declared that the possession of these must be supplemented by the possession of a "good character." It is in accordance with the intention thus expressed that in the regulations under which midwives are now admitted a good moral character is stipulated for, and it would be altogether illogical and absurd if the power to remove from the Roll on account of proved immorality were withheld. It is not, however, only the desirability of a right to remove undesirable persons from the official roll which we are now discussing. We are rather insisting upon the performance of the duty to remove such persons, both for the sake of the pregnant women who may come under the midwives' care, and for the credit of the women who have made midwifery their profession.

The Midwives Act sought to confer a benefit upon women at large by providing for them a body of trained and enrolled members of their own sex to attend them in labour. Incidentally, it deprived many members of the medical profession of a not unimportant percentage of their usual emoluments, while leaving them in the doubtful and unsatisfactory position of consultants to whom resort is to be had compulsorily in emergencies. It did more, however, than to provide for the training of midwives, and to hand over to them a share in a particular branch of medical practice. It conferred upon them a privilege, denied to medical men, of practising without any competition from the unqualified of their sex. Any man, however ignorant, however dishonest or immoral, may impose upon the ignorant by pretending to treat disease, so long as he does not pretend that he has medical qualifications. He may make a profit, indeed, by boasting that he does not possess them. But for the past five years women not certified under the Act have not been permitted to practise as midwives, even if they do not pretend to be registered as such. Midwives, therefore, now are members of a specially protected body. It is, however, of high importance that those enjoying unique and exclusive rights should be beyond question worthy to enjoy them. And in the case of midwives the privilege must be thoroughly deserved by the possession of an unblemished character. This is necessary for the sake of the patients treated and for the protection of the public. It is also, as is shown by the recent action of the Midwives' Institute referred to above, entirely in accord with the wishes of the midwives themselves. There is good cause for satisfaction in the fact that this representative body should have shown itself jealous for the honour of those for whom it is qualified to speak, and by its prompt action should have strengthened the hands of the Central Midwives Board in the fulfilment of its disciplinary functions.

◆

The New Salvarsan Products.

A COMMUNICATION was made on behalf of the Medical Research Committee to THE LANCET of April 10th with regard to the control which the committee, at the request of the Board of Trade, is exercising in the present national emergency over the French and British preparations of salvarsan which are issued for sale in this country. It was then announced that the committee were satisfied that the products tested biologically under their direction were not inferior in safety or in efficacy to the original German preparations. From a further communication, which we publish in this issue, it will be learned that both laboratory and clinical trials had proved satisfactory in the hands of the Medical Research Committee before the issue of the new salvarsan products was authorised, and as these have been now for some months at the disposal of the medical profession in this country, it seems to us quite timely that the committee should seek to collect from those who have had experience of their use a detailed record of their practical application.

We have nothing to add to the arguments set out by the Medical Research Committee to show that the making of accurate reports of all cases under treatment with the new salvarsan products will be of the greatest value, both now and hereafter. The results of the administration of salvarsan can at present be only imperfectly explained, and the only possible way to arrive at more perfect clinical treatment is by keeping careful notes of all cases, so that by collating those notes from time to time we may arrive at common lessons pointing the way to improvement. The communication which we publish this week says that, to appraise the significance of clinical experience after the employment of a particular batch of any given preparation, it is of great importance to have as complete a record as possible of the other cases which have been treated with the batch in question, for records of this kind, when referred to the scientific workers engaged on behalf of the Medical Research Committee in the biological testing of the products, would allow a study of the closeness of the correlation which may exist between the results of clinical observers on the one hand, and laboratory experts on the other. With such help it would become clearer whether the system of controls which has hitherto been applied, and which has followed the lines laid down by the experience of EHRLICH and his co-workers, requires any modification.

We join heartily in the request of the Medical Research Committee that records of this kind may be sent to the secretary of the committee, St. Stephen's House, Westminster. In the treatment of any disease by a series of preparations it is obvious that three possible sources of error and confusion must exist. The preparation, however carefully standardised, may not have constant virtues; the technique of administration will vary in its perfection; the patient has his fluctuating physiological properties and his idiosyncrasies. These sources of error and confusion can be restricted steadily, and can even be reduced to a point where they become negligible, but only by a steady comparison of carefully recorded results, and the more results that are available, and the greater the precaution that is taken to render them trustworthy, the sooner is the element of empiricism removed from practice.

Annotations.

"Ne quid nimis."

THE PLAGUE MENACE IN THE UNITED STATES.

WE have on several occasions drawn attention in these columns to the threatened danger of an invasion of the United States by plague. At the present moment the matter appears to be giving rise to some anxiety even in American official circles, and Dr. W. C. Rucker, Assistant-Surgeon-General of the United States Public Health Service, has lately set out certain facts and considerations bearing upon the subject in an article published in our American contemporary, *Public Health Reports.* Dr. Rucker points out that plague spreads more frequently from one country to another by water than by land, and that this diffusion is due to rats which travel on board ship from infected to healthy ports. At the present moment plague is widely spread over almost the whole of the known world, and as the United States are in frequent communication with foreign countries by shipping the arrival of infected rats is both possible and probable. Plague is at present occurring in the island of Cuba, and danger is also apprehended from infected ports in Brazil as well as from others in Peru and Ecuador. There is also frequent communication with the infected ports of India and the Far East as well as with those in North Africa and the Near East. No human cases so far as is known have occurred during the present year in the United States, but infected rats are still being found from time to time in the port of New Orleans and in a less degree at the Pacific port of Seattle. It has even been suggested that if careful search were made at other ports more infected rodents would probably be discovered. Dr. Rucker does not include in his enumeration of the sources of the plague danger the focus of enzoötic plague existing among the ground squirrels which infest the State of California, although up to quite recently infected animals have been caught in that region. There is risk that around the towns at least rats may become infected by entering the burrows of the ground squirrels and convey the infection into human dwellings. In discussing the action to be taken for resisting the invasion of the United States by plague, Dr. Rucker classes the measures under four headings—namely, enforcement of maritime quarantine, the prevention of the embarkation and disembarkation of rats at ports, the immunisation of the human population by inoculation with Haffkine's prophylactic, and lastly the rendering rat-proof of all dwellings and workplaces. As to maritime quarantine alone it cannot, he says, prevent the diffusion of the disease, and if carried out it must be done at the expense of commerce. The prevention of access of rats to ships, however valuable in itself, cannot be absolutely relied upon to keep away the disease altogether. As regards general protection of the human population by prophylactic inoculation, experience has shown that it is impossible to secure this to any great extent except where virulent and fatal epidemics have already caused ravages among the people and created panic. There remains, therefore, in Dr. Rucker's opinion, only the carrying out of general rat-proofing of all dwellings and places of business, a measure on which he believes implicit confidence can be placed to prevent any serious consequences even if infected rats should secure a landing and infect the local rat population. Lastly, Dr. Rucker expresses the opinion that persons who live or work in rat-proof buildings need have no fear of plague.

CHILDBIRTH AMONG CENTRAL AFRICAN TRIBES.

IT has been said that among savage tribes the act of parturition is less painful than among civilised people, and even that it is painless and free from danger, so that any assistance or medical aid is unnecessary. Dr. Carlo Pulieri, who for eight years practised in the Belgian Congo, has written an interesting letter on this point to *La Clinica Ostetrica* (May 30th), in which he declares that black women suffer as much as white and like them are subject to all the embarrassments of their condition, and that if they had the will and means to avail themselves of skilled assistance the mortality both of mothers and children would be sensibly diminished. Besides the fact that they have no faith in medical aid, the inveterate prejudices and beliefs of the natives prevent them having recourse to it. Among certain tribes, for example, childbirth is surrounded by the greatest mystery, nor may the husband be present, while the parturient woman, when the pains begin, betakes herself to some secluded corner in the forest with one of her friends and gives birth to her offspring there, seated on the ground with her back against a tree or leaning against her friend's breast. The placenta being expelled, the cord is cut with any knife that is to hand, the placenta buried, and the woman having been cleaned up with leaves, walks back to her hut with her baby in her arms. At other times labour takes place in the hut itself, but always on the ground in the position above described. The friend gets ready boiling water and performs any little services that previous experience suggests to her; bleeding is restrained by bathing with hot water and on the cut end of the cord some earth is placed or the powder of a particular kind of red wood mixed with palm oil. The same composition is also smeared on the large fontanelle, probably as a protection. All this, however, does not take place without groans, weeping, and gestures of despair, which afford very clear indications of the suffering the woman is undergoing. This description applies to a normal labour, but it is far otherwise if everything is not straightforward. A shoulder presentation, for example, would mean certain death for both mother and child. In less difficult cases, or where there are serious complications, the attentions of the friend are unfortunately exercised in such a manner as to attempt useless and dangerous manual efforts to deliver so that the woman's life is in serious peril. On one occasion a woman was brought to Dr. Pulieri at the hospital, who had been left for three days with the fœtal head out of the vagina, none of those present being able to extract the child. Manual delivery of the placenta is never practised, and no one troubles to ascertain whether expulsion is complete, the woman being often left for days with the afterbirth in the vagina or hanging half out. Shortly before he left an American missionary sent him a woman who had been suffering for four days. She had a temperature of 39·6° C., thready pulse, œdematous and bleeding genitals, enormously distended bladder, and the fœtal head fixed in the pelvis. Dr. Pulieri pushed up the head, emptied the bladder, and extracted the dead child, but the woman died a few hours afterwards. No one present at the labour knew anything about retention of urine, or would have possessed any means of preventing or relieving it. It is indisputable, says the writer, that labour among savage tribes is more easy than with us; conditions of climate, life, habits, and age eliminate many complications. Deformed pelves are very rare, the women are very young, and infection is not common among them. But these women suffer during labour, and although sepsis is rare there are cases in which it is severe and certainly due to lack of proper assistance.

THE TREATMENT OF ACUTE LOBAR PNEUMONIA.

IN a recent number of the *Polyclinic* Mr. A. J. Mathison describes what he considers an almost certain specific for the treatment of acute lobar pneumonia. Its use may be confidently expected to result in recovery, he says, unless the patient has already been ill several days. Of his own 65 patients all but one recovered; 13 had normal temperatures within a few hours. The treatment consists in giving the following mixture regularly from the moment of diagnosis until the temperature becomes normal :—

℞	Potassii iodidi	ʒi.
	Creasoti	ʒss.
	Spir. rectif.	ʒii.
	Ext. glycyrrh. liq.	ʒiii.
	Aquam ad	℥vi.

M. A tablespoonful to be taken every four hours.

The treatment produces an abortive type of pneumonia in most cases. Local applications to relieve pleuritic pain may be added; good nursing, though a welcome aid, is not essential; no powerful therapeutic measure, such as cold bathing, should be used with the treatment, which is as specific for pneumonia as quinine is for malaria. The diagnosis of Mr. Mathison's cases seems to have been made on the symptoms and physical signs they presented, without the aid of bacteriology. The simplicity of the treatment he recommends is no less striking than the success with which it would seem to have met in his hands and in the hands of other medical practitioners he names; a modern Tertullian might even be tempted to say of it, *Credo quia absurdum.*

AN EDUCATIONAL LUNCH-ROOM.

A VERY interesting experiment which at the present time might well be tried in this country has recently been started by the Department of Health in New York. An educational lunch-room has been opened for the use of the employees of the department, the object of which is primarily to provide a wholesome luncheon at cost price, and secondarily to educate the patrons in the subject of food and nutrition. From a copy of a specimen menu which we have received some idea is obtained of the luncheon served and of the methods followed to educate the customers in all questions relating to food values. This programme is divided into five columns. First is given the name of the dish, then the price, then the quantity, next the calorific value, and finally the protein content. A few examples are as follows: 4 oz. of lean beef are provided, costing 20 cents, the calorific value of which is 140 and the protein value 30; an average helping of potatoes, costing 5 cents, gives 150 calories and 4 grammes of protein; 3 oz. of ham, costing 15 cents, give 260 calories and 20 grammes of protein, and so on. These specimen meals show at once the foods which do or do not supply a sufficiency of calories or proteins, and the most economical way therefore in which each can be obtained. The experiment will be watched with interest, and though progress may possibly be slow yet the subject is more likely to be appreciated by this objective teaching of the lunch-room with its scientific menu or "food wisdom" notes than in any other way.

GASTRIC HEADACHE.

THE condition popularly known as "sick headache" or "bilious headache" has received little attention. Probably because the attacks are transient and do not endanger life or injure health it is regarded as one of those minor ailments scarcely worthy of the investigator. Yet it is a very common affection, and, as those who suffer from it well know, a most distressing and at times disabling one. In the *American Journal of the Medical Sciences* for May Dr. W. F. Cheney has brought forward evidence that at least one form of headache, probably known as "sick headache," is due to gastric disorder. This affection he terms "gastric headache." The symptoms are well characterised. The headaches are usually periodic, and may occur but once in a month or a week. They usually come on while the patient is in good health and are of variable duration, but rarely last more than 24 hours. He may awaken with the pain in the morning, which grows worse as the day goes on, or it may come on in the evening, persist during the night, and wear off after he rises. The pain may take the form of hemicrania or involve the whole head. Sometimes nausea and vomiting accompany the pain, giving rise to the term "sick headache," but in other cases no gastric disturbance is even suspected. On the other hand, there may be evidence of gastric disorder, such as belching or water-brash, or a sense of distension after meals, an abnormal appetite, or a persistent sour taste in the mouth. In a third group habitual indigestion of the hyperchlorhydria, atony, or chronic gastritis type is complained of. At the times of the headache the gastric symptoms are intensified. Dr. Cheney has investigated the gastric functions by means of test meals and found that the most frequent disturbance is loss of gastric motility. Gastric secretion may or may not be normal, but the important fact is delay of food in the stomach. If patients with this abnormality indulge in an unusually heavy meal or eat when tired or exhausted by mental or physical exertion headache is likely to result. The following is an example. A well-nourished man, aged 40 years, had suffered from headaches for seven or eight years. At first they occurred about once a week, but recently as often as every second or third day. Nausea usually accompanied headache, but rarely vomiting. The appetite was poor and much gas was belched after eating. Physical examination was negative, but after the Ewald test meal the total amount of stomach contents obtained was large, 176 c.c., and even after its removal a loud splash could be elicited. The total acidity was 72, with free HCl 36 and combined HCl 20. On inflation the greater curvature was found 4 cm. below the navel, but there was no peristaltic wave. The diagnosis was atony with hyperchlorhydria. A soft non-irritating diet with restriction of acid and highly seasoned foods was advised, and nux vomica was given after meals. As the patient spent long hours in an office he was urged to take more exercise out of doors. The headaches practically disappeared and recurred only at long intervals after an indiscretion in diet or work. Dr. Cheney does not suggest how the loss of gastric motility produces headache. The explanation seems to be that it leads to the formation of some toxins which are absorbed into the system. The foul tongue and breath—which may be observed in these cases and which he does not mention—point to this. He says that constipation is frequently present, but the condition is commonly observed in a most severe form without any constipation. However, a purgative, especially one which is an intestinal disinfectant, such as calomel, seems to shorten the attacks. Dr. Cheney has shown that these headaches are often due to gastric disorder, but we would suggest that the toxæmia on which they depend may also be due to some intestinal disturbance, or even to hepatic trouble—to revert to the old view.

THE NODAL OR A.-V. RHYTHM.

BY nodal rhythm there is meant synchronous or almost synchronous contractions of the auricles and ventricles. Instead of the latter succeeding the auricular systole at an interval of 0·12 to 0·16 second the two chambers contract together, due to the excitatory impulse reaching both chambers at the same time. This impulse originates at the A.-V. node, situated at the upper end of the bundle of His and equidistant, functionally, from each chamber. Such a dislocation of the "pacemaker" of the heart from its normal site the sinus, to this secondary and less rhythmic centre was thought at one time to be distinctly rare. But this opinion is now less strongly held since graphic methods of examination allow of its recognition. It gives rise to no symptoms, it does not influence rate, and for these reasons no doubt is less often recognised than would otherwise be the case. There are two conditions which may induce it. One is where the sinal rhythm is so slowed that this less rhythmic secondary centre is allowed the opportunity of initiating its otherwise dormant rhythm. The other is where the nodal rhythmic activity is enhanced in proportion to that of the sinus. Instances of both these kinds are known. In a recent issue of *Heart* Dr. E. E. Laslett reports one where the nodal rhythm is provoked through sinal slowing. Its rate was 53 to 59 per minute. Examples of heightened nodal rhythm replacing the sinus have been recorded by Cowan, and in several of his cases microscopical examination showed definite inflammatory changes involving the nodal tissue. Another case has been reported (Lea) where similar increased nodal activity occurred. In this case, however, its rhythmic rate so closely approximated to that of the sinus that the slight changes of sinal rate due to respiration, a quickening in inspiration and slowing in expiration, resulted in alternate phases of sinal and nodal rhythm, sinal (normal) rhythm occurring during inspiration, nodal rhythm during expiration. The nodal rhythm may not be without practical interest, in spite of its offering no subjective symptoms, since it has also been shown that phases of this character may occur at certain stages of chloroform anæsthesia. These latter observations have, at the moment, been confined to animals only, but their significance remains to be estimated clinically.

THE ETIOLOGICAL FACTOR IN CEREBRO-SPINAL FEVER.

IN another column we publish an article by Dr. R. Donaldson under the title of "A Contribution to the Study of the Etiological Factor in So-called Cerebro-spinal Fever." He makes various observations in regard to the bacteriology of cerebro-spinal fever which are not in accordance with the views generally held, but which are certainly suggestive, and if corroborated by other observers would necessitate considerable modifications of the opinions hitherto set forth as to the etiology and nature of the disease. Dr. Donaldson's observations were made during the outbreak of cerebro-spinal fever in Reading, and he examined the cerebro-spinal fluid in about 60 cases, so that his experience is considerable. At the outbreak of the disease he believed, like many others, that the meningococcus of Weichselbaum was responsible for the disease, but he now enunciates a new theory. He relates two cases, one of pyæmia with a history of preceding gastro-intestinal disturbance followed by a prolonged illness, and a second, which, while showing symptoms of meningococcal infection, might have been attributed to middle-ear disease followed by an abscess in the brain. From each of these cases similar organisms were isolated. Dr. Donaldson then proceeds to state that in all the fluids and purulent exudates from cases of cerebro-spinal meningitis which he examined he observed one common factor—namely, the presence of diphtheroid rods, together with Gram-positive and Gram-negative diplococci; all the various types of form were reproduced in cultures from the two cases to which we have just referred, and he therefore concludes that they were due to the same infective agent as was responsible for the epidemic that occurred in Reading. After a full description of the cultural characters of the organisms, their morphology and staining reactions, and the results obtained by inoculations in animals, the conclusion is arrived at that the causal organism of the epidemic dealt with was a diphtheroid rod closely related to the Klebs-Löffler bacillus. This rod appeared as a pleomorphous organism, which might give rise to Hoffmann-like forms, to what appear to be meningococci, &c. He maintains that this organism is very widely spread in nature in one of its most resistant forms, and "it is this form and not the meningococcal one which is transmitted from one to another." Dr. Donaldson's propositions deserve careful study, but we consider that further observations are necessary and hope that other bacteriologists may be stimulated, as opportunity arises, to investigate along these lines. The suggestion that the struggle of a new disease to win a place among epidemics is being witnessed requires further evidence before it can be accepted, but Dr. Donaldson has certainly given sufficient cause for attention and investigation.

ALKAPTONURIA, WASSERMANN'S REACTION, AND OSTITIS DEFORMANS ALKAPTONURICA.

IN a lengthy article of 130 pages illustrated with 19 reproductions of skiagrams and numerous curves and figures, Dr. G. Söderbergh[1] gives a new clinical account of the four cases of alkaptonuria hitherto described in Sweden, drawing particular attention to the fact that alkaptonuria without a previous syphilitic infection may give rise to a positive Wassermann reaction, and to a chronic deforming arthritis in many ways comparable to Paget's disease of the bones and joints. As is well known, alkaptonuria is characterised by the occurrence of homogentisinic acid (1–3–5–C_6H_3 (OH_2) CH_2COOH), otherwise known as dioxyphenylacetic acid, in the urine. This acid is partly endogenous in origin, or derived from the tissues, and partly exogenous, or derived from the proteins of the food. It is known to have two mother-substances or precursors—namely, tyrosin (1–4–$C_6H_4OHCH_2CHNH_2COOH$) and phenylalanin ($C_6H_5CH_2CHNH_2COOH$); if an alkaptonuric person is fed with lævo-rotatory phenylalanin, about 90 per cent. of the substance is excreted in the urine as homogentisinic acid. The disorder is known to be very chronic, mainly affecting males, and to be familial in incidence. Time was when alkaptonuria was regarded as a harmless type of abnormal metabolism, a metabolic "sport," as breeders might say. Söderbergh, however, lays stress on the troublesome and pathological associations it may have with the very rare disease ochronosis which often complicates its later stages, with the chronic arthritis to which Allard and Gross drew attention in 1909, with the cardio-vascular disease emphasised by Kolaczek in 1910, and with the occurrence of a positive Wassermann reaction in the blood. He gives a full account of the four Swedish cases of alkaptonuria with ochronosis, one of them a new case of his own. This patient, a peasant aged 42, exhibited a round kyphosis and rigidity of the whole dorsal and upper lumbar spinal column, thickening of the spine of the right scapula with waviness of its inferior margin, rounding of the lower margin, and increased thickness of the bone generally; the iliac crests were thickened also. Examined with the X rays, his bones generally and the basis cranii in particular showed increased translucency; the edges of the lumbar vertebræ were pressed outwards and thickened. Ochronosis and a strongly positive Wassermann reaction were found to be present. Söderbergh gives 48 pages to the relation between alkaptonuria and Wassermann's reaction, with experiments to illustrate the connexion between the two. His own patient gave a negative reaction after a month's treatment with mercury and iodide; then 15 grammes of racemic tyrosin were administered in six hours, and within 23 hours the patient once more gave a positive Wassermann reaction. The second patient gave a similar result when fed with tyrosin; the fourth patient gave a weakly positive reaction; while in the case of the third patient the tyrosin was by accident not exhibited at the right hours, and the negative reaction remained unaltered by its administration. None of the four patients gave any sign or history of syphilitic infection apart from the evidence furnished by Wassermann's reaction. The effect of 15 grammes of lævorotatory tyrosin on the reaction of two syphilitics and one healthy person was negative. Söderbergh quotes a series of laboratory experiments proving that increasing quantities of homogentisinic acid inhibit hæmolysis in hæmolytic systems either with or without antigen; increasing amounts of the acid may produce a kind of deviation of the complement, and may convert a weakly positive into a strongly positive serum and a negative serum into a positive. In relatively small amounts the acid may sometimes appear to promote hæmolysis; further light on this point is required. Phenylalanin gave results similar to those obtained with homogentisinic acid, but even more irregular. Attention is drawn to the fact that the production of the acid in the body, or at any rate its excretion in the urine, is very irregular at different hours of the day and on different days, whether the patient is starving or on a constant diet. These variations Söderbergh attributes to variations in the endogenous production of the acid; the acid is produced in the tissues and not in the intestine, and it is argued that other substances (such as phenylalanin and perhaps benzoquinone acetic acid) may also influence the Wassermann reaction in these patients. Söderbergh sums the matter up by saying that the amino-acid diathesis, of which alkaptonuria is one manifestation, may by itself produce a positive Wassermann reaction. He argues that very possibly the alkaptonuric lacks a ferment in his tissues to break down the homogentisinic acid, which is, after all, a normal product of metabolism. He connects Wassermann's reaction with the quantity and quality of the amino-acids present in the blood, and claims priority in this conception, which has since been elaborated (latterly without mention of his name) by Much, of Hamburg. Söderbergh quotes experiments to show that the administration of potassium iodide may lessen the excretion of homogentisinic acid by an alkaptonuric patient, the quantity falling from an average of 8·5 to an average of 5·5 grammes per diem. This may explain the conversion of a positive into a negative Wassermann reaction by iodide and mercury noted above. Discussing the symptomatology of ostitis deformans alkaptonurica, he gives very full details of the pathological changes in the bones and joints of the four patients he has examined; he finds comparatively little about the disease in the literature of alkaptonuria. All four exhibited kyphosis and stiffness of the spinal column resembling spondylitis deformans, with circumscribed or diffuse osteophytic thickenings of the pelvic girdle and scapula; the bones generally showed poverty in calcium salts, the results of the deformities rather than of the disease. The intervertebral discs were thinned and partially or even completely calcified. Söderbergh is unable to fit these bony changes into any of the recognised diseases of the bones. The prognosis *quoad vitam* is good, but bad *quoad valetudinem*; treatment by potassium iodide, possibly with mercury, is certainly to be recommended. He thinks that Paget's disease of the bones may prove on closer examination to be, like ostitis deformans alkaptonurica, primarily a disease of the intermediary metabolism.

---

THE SUPERSTITION OF FLAT-FOOT.

THE current view that most cases of static disability in the feet are due to giving way of the arch of the foot has been traversed by Dr. R. W. Lovett in a recent issue of the *Journal of the American Medical Association*. For the term flat-foot, he would substitute "foot strain." He, of course, admits that flat-foot exists, but would restrict the term to cases in which the ground is touched where the arch should be. Such feet may be rigid and resist correction, or when weight is not borne the arch may return to a certain extent. But flat-feet are not necessarily painful, and often are very serviceable—a point of some importance just now in the examination of recruits. In a research extending over several years Dr. Lovett examined the condition of 800 nurses' feet on entrance to a large general hospital, and again recorded the condition of those who developed any static disturbance during the three years' training. The nurses worked in day and night shifts in badly ventilated wards, and foot trouble was very frequent. Five or six with perfectly flat feet had no trouble whatever during the three years. On the other hand, one of the first cases that impressed Dr. Lovett occurred in a vigorous young woman with a foot so good that it was photographed as a type. She had so much discomfort from three months' work that she was incapacitated for two months, and finally had to leave on account of her feet. Yet there was no change in the shape of the foot or in its imprint, nor in any of the 800 nurses was a single case of change in the arch of the foot found. In every case the nurse stood for examination on a slab of plate glass with a mirror placed underneath at an angle so as to reflect the weight-bearing areas which appeared as greenish-white patches. These areas were sketched in the record and the amount of pronation noted. In some of the cases when painful symptoms arose the weight-bearing area had shifted slightly inward at the second examination—that is, the foot had rolled over a little over on its inner side without change in the arch, but in many cases there was not even this change. It follows that the static troubles which would ordinarily be described as flat-foot, "pronated foot," "weak foot," &c., are not due to any particular type of foot. Moreover, the pronated foot and the foot with a low arch proved slightly more enduring than the foot with a high arch. The inevitable conclusion, which has been borne out by Dr. Lovett's private experience, is that the pain and disability are due to muscular strain. He suggests that probably the ligaments become irritated by the failure of the fatigued muscles to support them, and that some degree of synovitis may arise in the tarsal joints. The foot trouble often followed an acute illness. Dr. Lovett regards the wearing of boots, which always to some extent deform the foot, as the predisposing cause. They practically always compress the forefoot and narrow the basis of support. But he considers the chief evil the curve of the sole of the boot which is made as if all feet had a rather low arch. Consequently a fair proportion of the community wear boots which impede the muscular action of the feet and do not compensate for this by supporting the arch of the foot, which is higher than that of the boot. In most cases this does no harm, because the individual is vigorous enough to overcome the disadvantage. From these views the treatment follows. The sole of the boot should have the curve which will support the arch of the foot. In the slighter cases where an obviously bad boot has been worn, it may be possible to get a boot with the requisite arch. More often the arch must be raised higher than this, which is readily done by splitting the leather forming the shank, removing the small piece of iron or stiffening which exists in most boots, and replacing it by a piece of steel with a higher and longer curve. If the foot is too pronated when the patient stands, especially if there are symptoms of strain at the inner side, the inner side of the heel may be made ¼ inch thicker than the outer, thus changing the bearing of the foot towards its outer border.

PROLONGED ANÆSTHESIA.

THE question asked by a correspondent, "Which is the longest period over which an anæsthetic has been known to be given for one operation?" has perhaps not much more than an academic interest. The practical form in which the question of length of possible anæsthesia arises is, "For how long can this particular patient be safely anæsthetised?" This is a problem which is frequently met, and the correct answer may be more confidently expected from an expert anæsthetist than from the physician or surgeon from whom it is generally demanded. It frequently happens that if an anæsthetist is confronted with a case of serious illness requiring operation, and is asked whether an anæsthetic can safely be administered, he has to give a qualified reply, such as "Yes, if the operation will not last more than such and such a time." In cases where the patient's general condition is normal the question of length of time rarely arises as a serious point, for most surgeons nowadays are fully alive to the importance of curtailing the operation period so far as is possible and compatible with care in operating. It is rarely, indeed, that any procedure requires four hours or more for its completion as in the case described by our correspondent. In ordinary work even long abdominal cases rarely exceed three hours, and one anæsthetist of wide experience has never had to administer for longer than three and a half hours for one operation in the whole of his career. The length of time that a patient could actually be kept anæsthetised and still recover would vary, of course, according to the nature of the operation, for it is the combination of operative shock and the effects of the anæsthetic that would be responsible if recovery did not ensue. And here the nature of the anæsthetic comes into the question. The modern methods of combined alkaloids, local analgesics, and general anæsthetics enormously extend the possible duration of safe anæsthesia. Many patients operated on by these methods are anæsthetic for several hours, for long, that is to say, after the operation has been finished. When the narcosis is of only a light degree anæsthesia can be safely maintained over very long periods, even without the aid of local analgesics, and simply by the administration of very diluted chloroform vapour. And probably if obstetric operations are included in our correspondent's query the record will be found to be easily held by a case of this kind. In a difficult confinement case, where it is desirable to postpone instrumental delivery as long as possible, the expert anæsthetist will maintain light narcosis for over six hours, finishing with full surgical anæsthesia during the seventh, and the patient will recover quite well. For experimental purposes animals have been kept continuously under chloroform during more hours than this and on repeated occasions, but this was with no concurrent surgical operation. A story associated with the question of long operations is told of two eminent Scotchmen. The late Sir B. X—— was informed by his anæsthetist, Mr. C——, that the patient, about to undergo laparotomy, was not a good subject for prolonged anæsthesia. "Very well," replied the great man, "but remind me when I've finished just to scrape that patch of lupus on his nose before he comes round." After an hour the patient's condition was poor and the anæsthetist duly drew attention to it. A little later he stated that the condition was serious. Imperturbably the surgeon continued an elaborate anastomosis, until some furious bleeding in connexion with deep-seated adhesions brought the patient to death's door. The anæsthetist now tactfully pointed out that spontaneous respiration had almost ceased. Soon life was extinct, but an elaborate stitching and detailed closing of the abdomen were solemnly executed. Now came Mr. C——'s turn. "You'll not forget, Sir B——, to scrape the corpse's lupus!"

A SPECIAL meeting of the Society of Medical Officers of Health will be held at No. 1, Upper Montague-street, Russell-square, at 5 P.M., to-day, Friday, June 25th, when a discussion will be opened on Thrift in Our Food-supplies, by Dr. H. Meredith Richards, vice-chairman of the National Health Insurance Commissioners of Wales. The meeting and discussion will be open to all persons who are interested in this important question.

THE Cavendish lecture, on the Great Bowel in Health and Disease, by Professor Arthur Keith, will be delivered at the West London Hospital to-night (Friday, June 25th), at 8.15 P.M., and will be followed by the annual conversazione.

THE annual general meeting of the Poor-law Medical Officers' Association of England and Wales will be held on Tuesday, July 6th, at 4 P.M., in the Council Chamber of the British Medical Association, 429, Strand, London, W.C. The presence of all Poor-law medical officers is invited.

Sir Alfred Pearce Gould has been elected Vice-Chancellor of the University of London for the year 1915–16 in succession to Sir Wilmot Herringham.

THE Royal Society of Medicine has conferred on Sir John Williams, Bart., M.D., G.C.V.O., the Honorary Fellowship of the Society.

THE MANUFACTURE OF SALVARSAN PRODUCTS IN ENGLAND AND FRANCE.

A COMMUNICATION was made on behalf of the Medical Research Committee to THE LANCET of April 10th with regard to the nature of the control which the committee, at the request of the Board of Trade, has been exercising during the present emergency over the French and British preparations of salvarsan which are issued for sale in this country. It was then announced that the committee were satisfied that the products tested biologically under their direction were not inferior in safety or in efficacy to the original German preparations. It may be remarked here in addition that satisfactory results of clinical trials, as well as the results of the laboratory tests for toxicity, were in the hands of the committee before the issue of these products was authorised. The preparations in question have now for some months been available for use by the medical profession in this country, and it appears desirable to the committee that they should seek an opportunity of collecting from those who have had and are now having actual experience of the use of these British and French salvarsan products as complete a record as possible of the results of their practical application.

It is well known that many of the incidental results which may follow the administration of salvarsan can at present be only imperfectly explained. A certain proportion of unfavourable results, including some fatal results, is known to have followed the use of the original German products. While some of these have been explained as being due to imperfect precautions with regard to the purity of the water used in the injection, others have been attributable only to a supposed idiosyncrasy of the patient.

In order to appraise the significance of a favourable or of an unfavourable clinical experience found in the use of a particular batch of any given preparation, it is of great importance to have as complete a record as possible of the other cases which may have been treated with the batch in question. Records of this kind, when referred to the scientific workers engaged on behalf of the Medical Research Committee in the biological testing of the products, would allow a study of the closeness of the correlation which may exist between the clinical results on the one hand, and their laboratory results on the other. Such a comparison between the two kinds of experience would allow a determination of the question whether it is desirable to add to, or to modify in any way, the system of controls which has hitherto been applied, and which has followed the lines laid down by the experience of Ehrlich and his co-workers.

The committee venture to urge that members of the medical profession would be performing a service of national importance, in the present emergency, by keeping accurate records of cases in which the new preparations are used, and by placing such records at the disposal of the committee for their private information and guidance. Particular stress must be laid upon the desirability of recording in every case the name of the preparation used and the serial number applied by the manufacturer to the particular batch employed, together with full details as to dosage, the precautions taken to ensure purity of the water used, and finally, the results of the administration, both as regards therapeutic efficacy and the presence or absence of special incidental symptoms.

It is requested that records of this kind may be addressed to the Secretary of the Medical Research Committee, St. Stephen's House, Westminster.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Irish Medical Association.

AT the annual meeting of the Irish Medical Association last summer a resolution was carried directing the council to appoint a committee to make suggestions for the reorganisation of the association. A committee was appointed and presented a scheme to the council in April last. The council adopted the scheme with a few amendments, and articles and by-laws to make it effective were drafted. The chief change suggested was the reduction of the council from about 80 members to less than 50 by the elimination of most of those elected by the body of members as a whole as distinct from those representing branches. It was also proposed to abolish the offices of honorary secretary and honorary treasurer. To make the changes law it was necessary that they should be adopted at two special meetings of the association. At the first of these meetings the new articles of association had been carried and the greater part of the by-laws, when it was discovered that there was not a necessary quorum present for the transaction of business, and the proceedings were rendered useless.

The annual meeting of the association was held on June 16th at the Royal College of Surgeons, under the presidency of Mr. F. W. Kidd. There was a good attendance of members. The annual report of the council stated that the number of members had increased. Nine members had been removed from the list for accepting and persisting in retaining the position of "medical adviser" or "certifier" under the Insurance Act. The statement of accounts showed a credit balance of £465 2*s.* 4*d.* The report referring to the work of the reorganisation committee said that the report to the council of the association, after some amendments, had been referred back to [have the articles and by-laws drafted. The secretary informed the meeting of the fiasco of the special general meeting. After some discussion the reorganisation committee was reappointed, and the council was directed to summon special general meetings at convenient dates in the autumn to consider the draft articles and by-laws. Following the adoption of the report of the council there was a desultory discussion with regard to proposed coöperation with the British Medical Association, but no decision was arrived at. The following officers were re-elected: Mr. F. W. Kidd, president; Dr. Leonard Kidd, Mr. James Keating, Mr. J. B. Story, and Dr. J. Geraghty, vice-presidents; Dr. T. Donnelly, honorary secretary; and Dr. H. U. Byrne, honorary treasurer.

After a debate on the question of appointing a committee to collect evidence and report on Poor-law reform, the question was referred to the existing Poor-law subcommittee of the Irish Medical Committee.

The following resolution was passed unanimously:—

> This association protests against the appointment of medical advisers or part-time certifiers under the National

Insurance Act, and is of opinion that any medical man accepting and retaining such appointments should not be met professionally by consultants or other medical practitioners.

A Meeting of Medical Delegates.

A meeting of delegates of the medical profession of Ireland was held at the Royal College of Surgeons on June 15th, Mr. R. J. Johnstone being in the chair. Having reconstituted the Irish Medical Committee for another year, the meeting re-affirmed the decision that all medical certificates under the Insurance Act should be issued by the medical attendant of the insured person. A discussion took place with regard to tuberculosis work under the Insurance Act, and it was pointed out that the policy pursued by the Insurance Commissioners of excluding the medical attendant from any share in the administration of the sanatorium benefit prevented the discovery of early cases of the disease. A resolution was passed demanding that medical referees under the Insurance Act should notify the patient's medical attendant of the day and hour of a proposed visit to an insured person. Discussion also took place with reference to professional relations with "medical advisers," and it was held that no medical man should enter into consultation or other professional relation with an "adviser."

Royal Medical Benevolent Fund of Ireland.

The annual meeting of the Royal Medical Benevolent Fund Society was held on June 16th in the Royal College of Physicians. Sir John Moore read the annual report, which stated that the number of applicants during the year had been up to the average, but the aid given was far short of their requirements. The receipts had fallen considerably, and it had been necessary to recommend the curtailment of some of the grants. The total number of applications considered was 85; of these, 76 were from widows of medical men, six from or on behalf of orphans, and three from medical men themselves. The total amount of the grants recommended since last distribution was £1138. The honorary treasurer, Sir Stewart Woodhouse, read the treasurer's report. Including a balance of £476 6*s*. 8*d*. brought forward from the preceding year, the income of the society for the year ended April 30th was £1991 11*s*. 3*d*., a decrease of £180 7*s*. 1*d*. This decrease was doubtless owing to the pressing claims of the war now in progress upon the subscribers. On the credit side of the account the disbursements were £1461 3*s*. 8*d*.—viz., grants, £1347; miscellaneous payments, £114 3*s*. 8*d*.

The Royal College of Surgeons in Ireland and a Proposed Boycott.

The secretary to the Council of the Royal College of Surgeons in Ireland has distributed to the Fellows and Licentiates of that body copies of a correspondence which has recently passed between the Council and one of the Fellows. Mr. A., a Fellow, asked for an expression of opinion of the Council as to what his attitude and conduct should be in the following circumstances: His colleague, Mr. B., had accepted a "medical advisership" under the National Insurance Commissioners, thereby violating an agreement by which he had bound himself, as did the great majority of medical men in Ireland, not to accept any such office without the approval of the local medical committee, and then only if the conditions were in accordance with the declared policy of the Irish Medical Association. Consequent on Mr. B.'s accepting this office a meeting of the medical practitioners of the county had been held, and Mr. A. stated that he had been warned that unless he consented to boycott Mr. B. he would himself be subjected to boycott. He asked the Council for guidance. In reply, the Council states that unless Mr. B. can prove that he signed the undertaking under a misapprehension as to its scope and meaning, his violation of his written undertaking calls for the severest condemnation. As to a proposed boycott of Mr. B., the President and Council could not express any approval of such action. The letter severely condemns the action of any medical man who interferes in a professional capacity with the patients of other medical men, and by promising that the Council will deal severely with this offence, if proven, the communication will be of considerable assistance to the medical profession.

Belfast Water-supply.

The water in store in the Belfast reservoirs amounts at present to 1957 million gallons, which is 63 million gallons less than the storage on the corresponding date of last year. On a similar date in the dry year of 1911 the quantity available was 1811 million gallons. It appears that not only has the proposed reservoir in the Silent Valley of the Mourne Mountains not been begun, but that even if it were commenced it would not be completed for seven years; in the meantime people are in dread that, as before, Belfast will be placed on an intermittent supply. At a meeting of the Water Board, held on June 17th, the chairman quietly announced that, as soon as the war was over, the Board hoped something would be done. The Commissioners' inactivity was sharply condemned by certain members of the Board.

The King Edward Memorial Building, Belfast.

This memorial building, which will serve as an adjunct to the Royal Victoria Hospital, was opened recently by His Excellency the Lord Lieutenant of Ireland. The building owes its inception and erection to Lady Pirrie, who, as Lady Mayoress of Belfast in 1896, was instrumental in raising a sum of £100,000, to which she and Lord Pirrie contributed very handsome sums, and also raised a further sum of £48,000 as an endowment fund. Mr. J. Milne Barbour, D.L., said that in anticipation of the great demands which would probably be made in the near future on hospital accommodation for the treatment of sailors and soldiers wounded while fighting for their country, it had been decided to place the new building at the disposal of the hospital authorities at the earliest opportunity. Sir John Byers, chairman of the medical staff of the Royal Victoria Hospital, said that when the building was fully furnished the medical staff would be provided with some of the most recent practical adaptations of those sciences that were ancillary to medicine for the diagnosis and treatment of disease, and he hoped that the building would witness discoveries which would advance our knowledge in medicine and surgery. He pointed out the important work which would be carried on in the departments of vaccine therapy, electricity, and biochemistry under the direction respectively of Dr. T. Houston, Dr. J. C. Rankin, and Dr. J. E. MacIlwaine, and concluded by saying that without such institutes as that in which they were assembled those discoveries would never have been made by which our sailors and soldiers had been kept in a healthy and fit state and had been preserved from such diseases as typhoid fever, dysentery, and lockjaw.

June 21st.

THE BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND.

MACHINERY FOR DISTRIBUTION OF FUNDS IN BELGIUM.

WE have now received the detailed report of the session of the Aide et Protection aux Mèdecins et Pharmaciens Belges Sinistrés on May 6th, which continues the story of the distribution of funds by the Belgian Society. A financial statement showed that by the end of April 65,000 francs had been received and a little over 45,000 francs had been spent, great discretion having been obviously exercised in making the grants. The kind of case relieved has been fully illustrated already.

At this session the cases were mentioned which had already been found deserving of continued monthly relief, in accordance with the principle adopted at the last session, and the brief notes upon the selected objects of special help reveal some truly tragic situations. All the grants of money proposed by the eleemosynary subcommittee were unanimously adopted by the committee.

We have received through Professor Jacobs a statement of the financial position of the Belgian Society up to June 10th, which shows that the funds are still lasting out, but necessarily the disbursements are rapidly increasing. The Aide et Protection aux Médecins et Pharmaciens Sinistrés had received by the end of the first week in June 77,000 francs, and had disbursed 60,000 francs, while the extraordinarily modest expenses of administration amounted to less than 500 francs.

Since this date a substantial sum of money has been sent by the British Committee to the Belgian Committee, so that Dr. V. Péchère (president) and his admirable colleagues, M. A. Delacre, Dr. Laruelle (secretaries), and Dr. H. Coppez (treasurer) will be able to continue with good heart to meet the increased calls upon their resources.

THE WEEK'S SUBSCRIPTIONS.

The week's subscriptions include the handsome contribution from the New South Wales Branch, B.M.A., of £500, making with previous donations a total of £728 received from this generous source.

	£	*s.*	*d.*
Dumfries and Galloway Division, B. M. A. (per Dr. J. D. Robson, Hon. Sec.)—			
Dr. Robertson	0	10	0
Dr. H. Bryan Densham	5	5	0
Dr. A. G. Peter	2	2	0
Birmingham Local Committee (per Dr. Saundby, Hon Sec)—			
Dr. A. E. Richardson	5	5	0
Aberdeen Division, B.M.A.—			
Drs. Pirie, A. H. Lister, J. F. Christie, Croll, M. K. Booth, F. K. Smith, Alex Low, John A. Milne, Col. Mitchell, Drs. Gordon, Levack, Geddie, Stephen, Davidson, Smith, Slessor, J. P. Mitchell	28	0	0
Dr. Mary O'Brien	1	1	0
Dr. G. D. H. Carpenter	1	0	0
New South Wales Branch B.M.A.	500	0	0
North of England Branch of Fund (per Dr. James Don and Mr. A. S. Perceval, Hon. Secs.) (fifteenth donation, total £728 19*s.* 7*d.*)—			
Dr. J. J. Carruthers...	1	1	0
Dr. D. S. Park	1	1	0
Dr. F. Hunton	1	1	0
Dr. W. J. Carmichael	2	2	0
Mr. A. Williams	1	1	0
Mr. A. Mortimer	0	10	6
M. P. S.	0	3	0

Subscriptions to the Fund should be sent to the treasurer of the Fund, Dr. H. A. Des Vœux, at 14, Buckingham-gate, London, S.W., and should be made payable to the Belgian Doctors' and Pharmacists' Relief Fund, crossed Lloyds Bank, Ltd.

THE APPEAL FOR SURGICAL INSTRUMENTS.

The Master of the Society of Apothecaries begs to acknowledge the receipt of surgical instruments kindly contributed by the following donors since the publication of the last list:—

Dr. Gordon Brown, Chigwell, Essex; Barnsley Division of the B.M.A., second donation, per Dr. R. F. Castle.

Instruments should be sent to the Apothecaries Hall, Blackfriars, E.C.

THE NATIONAL INSURANCE ACT.

London Panel Committee: War Emergencies and Local Coöperation.

THE London Panel Committee on June 22nd discussed the formation of local associations of practitioners on the panel. It was urged by the General Purposes Committee that such bodies would be of great value in dealing with problems peculiar to localities, in removing local grievances, and in preserving the interests of practitioners on the panel. In each area coöperative arrangements might be made for weekly and periodical holidays; rotas of medical referees might be appointed to advise in difficult or doubtful cases; in districts in which sickness incidence was heavy practitioners might encourage the provision of lectures on health and work for sanitary reforms tending to benefit health. Negotiations with hospitals and arrangements for specialist consultations might sometimes be better carried out by a local association. The committee passed a resolution expressing the opinion that practitioners on the panel in the various areas of London should be grouped under district panel associations.

A statement was submitted showing that the number of practitioners on the panel resident in London was 1550, of whom 457 were registered since 1900, and presumably were eligible for service with the Forces. The number of practitioners on the panel at present absent on military duty was 125. The General Purposes Subcommittee had pointed out that it would appear that only about one-quarter of the eligible practitioners were actually serving with the Forces, and that the difficulty was a fear that on returning practitioners would find their practices much depleted by reason of the transference of insured persons to other lists. The Panel Committee passed a series of resolutions expressing the opinions that:—

1. The right of an insured person to transfer should be temporarily suspended.
2. That practitioners on the panel should collectively arrange to release an adequate proportion of their number for service with the Forces.
3. That in the event of a colleague accepting a commission the practitioners undertaking the treatment of the persons on the list should, in normal circumstances, permit the colleague to retain 50 per cent. of the income from the insurance practice.

A detailed scheme embodying these resolutions was also approved.

The Local Medical and Panel Committees and the War.

At the conference of representatives of Local Medical and Panel Committees convened by the British Medical Association on June 16th the number of motions placed on the agenda with regard to insured persons who may be discharged from the services incapacitated for work showed the serious apprehension felt by medical men on the panels as to their future position and the effect likely to be produced upon it by the war. The original motion to consider the questions arising having been assigned to the chairman, those set down by various Local Medical and Panel Committees dealt with various aspects of the case and suggested remedies. From Liverpool came the proposal that Parliament should make some grant to practitioners on the panels to compensate them for the serious charge likely to be imposed upon them by the return of many of their "best lives" as broken and disabled men. The Croydon Committee asked for an increased capitation fee in respect of such patients, the Nottingham Committee suggesting, as an alternative for a higher rate of remuneration, payment for work done, "in view of the fact that circumstances have arisen which were not contemplated when the existing terms were arranged." The Northumberland Panel Committee, by the terms of its motion, protested against the direction contained in Memo. 210 I.C., making insured persons returning to civil life free to select their method of obtaining medical treatment as though newly entering upon insurance. This, it was pointed out, would tend to increase the number of unallotted patients. The approval of the Insurance Act Committee of the British Medical Association had already been given to an arrangement for the reinstatement of the insured person to the list of the medical man attending him before his enlistment, subject to the right of the insured person to change his medical attendant, and to that of the medical man to refuse to reaccept the insured person.

The New Certification System.

One of the most interesting of the documents circulated among the representatives of Local Medical and Panel Committees with a view to the conference contained information as to the attitude of the Approved Societies with regard to the certification of chronic cases. A letter had been sent to the societies calling attention to the way in which the subject is treated in Memo. 211 of the Insurance Commissioners, and to the hardship, accentuated by the stress of war conditions, needlessly caused by the requirement of weekly certificates. To this letter 45 replies had been received, of which 31 intimated that weekly certificates were considered by the societies affected to be unnecessary, or were likely to be declared so. Nine societies merely acknowledged the letter or stated that it would receive consideration. Five replies were of an unfavourable character, but in some of these cases further correspondence appeared to be likely to obtain the concessions asked for. On the whole, therefore, the societies may fairly be said to take a reasonable view of the matter, in which they are not asked to sacrifice any principle of importance affecting either their own interests or the personal interests of their members.

The Panel Medico-Political Union.

At the recent annual general meeting of the Panel Medico-Political Union, now entering the second year of its existence, the result of the elections of officers and council for the coming 12 months was made public. Among those re-elected was the chairman, Dr. W. Coode Adams, the other officers chosen being: Vice-Presidents, Mr. J. A. Angus, Dr. H. J. Cardale, Dr. H. G. Cowie, and Mr. R. J. Farman; treasurer, Dr. G. R. Young; trustees, Dr. W. Coode Adams, Dr. G. B. Batten, and Mr. F. H. Lane. In addition to these, 30 names of practitioners chosen to be members of the council were announced. In his address the President dwelt upon the intention of the Union to exercise political influence on behalf of members of the panels and to obtain the support of members of the House of Commons by exercising such influence on their behalf, or the reverse, in their constituencies. Among objects aimed at would be the obtaining of better representation upon Insurance Committees for panel practitioners, and also more direct representation for insured persons. The holding back of money due by the action of suspense slips was a grievance to which special and immediate attention would be directed, as well as the question of insured persons returning from the war invalided.

Coventry Insurance Committee.

The Coventry Insurance Committee at a recent meeting considered the question of surcharges made by the Treasury auditor in respect of expenditure incurred through representatives of the committee attending certain conferences connected with insurance matters. A resolution in terms recommended by the finance subcommittee was passed protesting against the surcharges, and representing that the expenditure disallowed was reasonable and necessary to the carrying out of the committee's work, there being, moreover, no statutory delimitation of the expenses which might rightly be incurred. It was argued in the course of the discussion that it was of the utmost importance to the committee that it should be in touch with other insurance committees, and that this object was attainable only through taking part in the conferences referred to. Important criticism of the financial provisions of the Insurance Acts for the treatment of tuberculosis took place at the same meeting. It was pointed out that in the provision of treatment, institutional and domiciliary, expenditure was being incurred and undertaken at Coventry which could not safely be continued, a medical member of the committee expressing the opinion that the situation arose through no fault of the committee, "for at the beginning of the Act people were promised all sorts of benefits, which, however, had been shown to be quite impossible." The speaker submitted that the only solution of the difficulty would be the provision of money by the Treasury on a much larger scale. Under the Act the amount of consumption and the extent of the curative measures necessary had been very much under-estimated. The chairman, in making observations to a similar effect, argued that the whole basis of the scheme was wrong. With reference to suggestions made that the prevention of consumption by sanitary measures would be found more effective than attempts to cure it, he was of the opinion that before this could be done the amendment of several Acts of Parliament besides the Insurance Acts would be required. The fact remained, he said, that the work of the sanatorium benefit subcommittee had reached such a stage in its development that the subcommittee could not keep on under existing conditions, and he wanted the insured public to understand that the Insurance Committee had no desire to limit the rights of any insured person, but that it was bound, having regard to its commitments, to adopt a different attitude.

MEDICINE AND THE LAW.

Modern Echoes of a Famous Crime: the Trial of the Stauntons.

NEARLY 40 years ago, in September, 1877, four persons, Louis and Patrick Staunton, Elizabeth, wife of Patrick Staunton, and Alice Rhodes, her sister, were convicted at the Old Bailey for the murder of Harriet, wife of Louis Staunton, and were sentenced to death by Mr. Justice Hawkins, who, according to such public opinion as found immediate expression, had brought to a successful issue the first trial for murder conducted by him. The capital sentences, however, were not carried out, a result largely due to the efforts of the medical profession and of THE LANCET. The case and its history have recently received prominent notice in the *Cornhill* from the pen of Sir Edward Clarke, who defended Patrick Staunton, and who in his résumé of the trial made criticisms of a severe character upon the late Lord Brampton, better known as Mr. Justice Hawkins. We are not here concerned with the views expressed by one of the most able and eloquent advocates of the last generation upon a judge who, whatever his demerits, had many shining qualities, but we did at the time of the "Penge mystery" interest ourselves considerably in the fate of the Stauntons and Alice Rhodes, and in securing for the medical evidence given on their behalf the recognition which the judge had denied to it.

These things contributed not a little to saving from the gallows four persons, who by whatever acts of cruelty and immorality they might severally have deserved public execration, certainly had not murdered Harriet Staunton by starving her to death, the only way in which they were accused of committing the crime charged against them. Whatever opinions leaders of the Bar may have held of Mr. Justice Hawkins during his long career as a judge in civil or in criminal cases, of his fairness or unfairness, of his clemency or the reverse, he undoubtedly made a very ill-advised effort to secure conviction for the capital crime in a case in which the medical evidence was of supreme importance and in which medical evidence of the highest quality was opposed to the conclusion at which he desired the jury to arrive. In order to do this he was compelled to belittle the expert evidence called for the defence, and he virtually ignored it. He practically omitted from his summing-up all appreciation of the testimony of Dr. J. S. Bristowe and Dr. J. F. Payne, respectively a most wise physician and a most careful pathologist, and alike scrupulously careful observers; and he accordingly obtained a verdict which the medical profession immediately recognised as being contrary to justice. The whole of the squalid story of the Staunton case has been admirably compiled by the late Mr. J. B. Atlay.[1] Harriet Staunton was treated in different degrees by the four persons named in the indictment with abominable neglect and cruelty, but, as THE LANCET of Oct. 6th, 1877, put it in a leading article commenting upon the trial: "It must obviously be impossible to prove murder by starvation without first showing death by starvation." As we then stated, holding an opinion from which we see no reason to depart, the attempt to affirm the primary proposition failed. The post-mortem appearances were not consistent with the hypothesis of death from the cause assigned. They afforded irresistible evidence of other factors at work, although it was not, owing to the defective manner in which the body was examined, possible to say which of several morbid conditions proved fatal to life.

---

[1] Trial of the Stauntons. Edited by J. B. Atlay, Barrister-at-law. Wm. Hodge and Co.

We do not suggest that the verdict actually arrived at by the jury was unsupported by medical evidence entitled to due consideration. Several medical practitioners of standing, two of whom were called as experts, supported the view that starvation caused the death of Harriet Staunton, but the ignored scientific evidence was beyond question better qualified to command attention than that which secured the adverse verdict, and the fact that Dr. Bristowe and Dr. Payne had not seen the deceased in life, or her body after death, did not materially discount the value of their opinions, as the judge in his brief reference to their evidence suggested.

Expert witnesses as a rule rely upon the facts described by others in forming their opinions, and if the observers are qualified by training the expert's opinion rests upon a satisfactory foundation. In this instance the value of the medical evidence for the defence might have been said to have gained, rather than to have lost, by its dependence upon that adduced by the Crown. Those who gave it accepted the sworn statements of witnesses for the Crown as to what they had seen or had failed to observe, but drew the scientific deductions. Perusal of the evidence many years after, indeed, suggests that in his later years the same judge would probably have taken a different course, either devoting more time to criticising and weighing the evidence of Mr. Payne and Dr. Bristowe even if only to endeavour to demolish it, or recognising its force in preventing the establishment of the case for the Crown "beyond any reasonable doubt." He must also have been aware that he had shut out upon technical grounds the evidence for the defence of a very highly qualified witness, although he may have assumed that he with the others would be reduced to permanent silence by the jury's verdict.

A repetition of that which occurred in 1877, when the four prisoners solemnly condemned to death for Harriet Staunton's alleged murder were reprieved almost immediately, is not likely to occur now. It might do so, of course, but the progress of science, protecting human life in many ways, has added certainty to the results of medical investigation into causes of death and similar matters, and, with greater sureness that the truth will have been arrived at, weight is given with greater confidence to the best medical evidence by judge and jury alike. We need only refer to the trials of the murderers Crippen and Seddon in order to remind ourselves of the public confidence in the establishment of justice by medical evidence in cases where the material facts are incomprehensible so far as the general public is concerned. There was a perceptible agitation for reprieve in each of these cases, but it rightly came to nothing.

THE SERVICES.

Royal Navy Medical Service.

THE undermentioned have been granted temporary commissions as Surgeons in His Majesty's Fleet:—Dated June 16th: William Lovell and Charles Stuart Ogilvy. Dated June 17th: Edwin John Tongue.

Army Medical Service.

Major Sir Berkeley G. A. Moynihan, R.A.M.C. (T.), to be temporary Lieutenant-Colonel (dated June 10th).

Royal Army Medical Corps.

Captain William McConaghy is seconded for service with the Egyptian Army (dated June 5th).

Temporary Captain Sydney G. L. Catchlove relinquishes his commission (dated June 11th).

Temporary Lieutenant Thomas M. Watt relinquishes his commission (dated March 1st).

The undermentioned to be temporary Majors:—Dated May 27th: Alexander Johnstone. Dated June 7th: George Harry Melville Dunlop and Henry Alexis Thomson.

The undermentioned to be temporary Captains:—Dated May 1st: Arthur George Whitehorne-Cole. Dated May 22nd: Walter Sydney Lazarue-Barlow.

The undermentioned non-commissioned officers and men of the Canadian Army Medical Corps to be temporary Lieutenants:—Dated May 26th: Sergeants Robert Beattie Martin, Harry Roy Smith, Paul Michael O'Sullivan, Louis Edwin Williams, David Edmund Staunton Wishart, and Gerald Allison; Corporals Clifford M. Keiller, David Emerson Scott, and Stanley Stafford Ball; Lance-Corporals Herbert Carl Martin and Thomas Harold Douglas Storms; Privates Thomas Daily Cumberland, Donald Thomas Fraser, Richard Collier Coatsworth, Harry Karl Groff, Louis Emile Belcourt, Morley Edward Gorman, Maurice Round Helliwell, Thomas Harold Crews, William Ray Hodge, Harold Parrish Hamilton, Frederick Walter Clement, Athol Alexander Moon, Stanley Young Walsh, Arthur McKnight Bell.

The undermentioned to be temporary Lieutenants:—Dated April 14th: Harold Robert Dew, Robert Kenneth Birnie, Jack Morlet, Albert Weigall, George Clifford Scantlebury, James Garnet Sleeman, William Alfred Leslie Harrison Henderson, Albert Wilber Bretherton, Cyril Checchi, Frank William Augustus Ponsford, Walter Cecil Marsden, Thomas Edwin George, Alfred John Trinca, Raymond William Ryan, Nigel Lovat Prichard, William Arthur Bowman, William Alexander Hamilton Birrell, William Rogerson, Wilberforce Stephen Newton, and George Chadwell Bury. Dated April 20th: Francis William Stone, Frank Harold Looney, Arthur Ernest Stenning, Michael Harold Sorokiewich, Robert Welton Hogg, Johnston Hughston, Charles Humphrey Lloyd, Cecil Gordon McAdam, and Roy Baldwin Minnett. Dated May 1st: William Moore Skipwith Robinson. Dated May 10th: John Joseph Middleton. Dated May 13th: Dominick John Cannon. Dated May 20th: Samuel Lloyd Corry, Malcolm Macnicol, Percy Templeton, Edgar Roe Lyth, Stephen Galt Trail, Frank Melville Harvey, and Tudor Benson Evans. Dated May 21st: Ellis Gordon Goldie, James Murray Duff Mitchell, George Peter Taylor, Edmond Ryan, John Charles Michell, John Low, Edward Beresford Collings, Albert Edward Blackburn, Francis Anderson, John Anderson, James Montgomery Anderson, Edward Scott White, Thomas Trevor Apsimon, Maurice Aloysius Power, Henry Glendinning Davison, John Clark, William O'Brien, Thomas Kirkwood, Allen Edgar Thompson, Augustus Beauchamp Northcote, James Samuel Richard Weir, Robert Charles De Lacey, Henry Richard Hurry, and Claude Robinson Lucas. Dated May 22nd: Frederic William Waudby Griffin, Alexander Newton Clemenger, Daniel Charles Evans, and Herbert Frank Willington. Dated May 24th: Israel Allaun, James Lawson Williams, William Henry Warwick, Roy Darley Clayton, Gerald Henry Davy, Frank Ernest Reynolds, and Charles Brehmer Heald. Dated May 25th: James Cunningham, Lancelot Gordon McCune, Bernard Geoffrey Klein, James Davidson MacKay, Henry Donald Welply, William Taylor Buchan, Ernest Coleman, Robert James Allsopp, John Gordon Smith Macpherson, John Proctor, Donald McIntyre, David Charles Welsh, Arthur Leslie Walters, William Ledingham Christie, John Lyn Dimond, Dan Arthur Powell, Arthur Edward Clarke, Robert Hugh Drennan, Wilfred Angel Easton, Arthur Noel Houghton, Herbert Playford Sheppard, Raymond Alexander Hannay Atkinson, Allan Massey, William Rice Meredith, Francis Joseph Sadler, Spencer Churchill, and Douglas Allan. Dated May 26th: Watts Edmondson, Charles Salkeld, Arthur John Clayton, John Koble Milne Dickie, Hew William Scott-Wilson, and Arthur Geoffrey Shera. Dated May 27th: Arthur Edward Lyster, James Lochhead Gregory, Lester Ernest Ashley Emile, William Minty Badenoch, Richard Nunn, Sidney Winslow Woollett, Thomas Hutchinson, Andrew Philip, Nelson West Jenkin, Adam Brown, Arthur James Lewis, Hugh James McCurrick, Charles Samuel Woodd, William Edward Nickolls Dunn, Patrick Aloysius Doyle, Kirsop Bainbridge James Vickers, George Brown Crawford, David Fettes, Barron Norman Sinclair, James Leslie Callaghan, and William Hunter Brown. Dated May 28th: Arthur Hill Laird, Malcolm Mauson, Harold Willis Scawin, Robert Scott, Mark O'Brien, Kenneth Fraser, Leslie Gordon Tait, George Kirkwood Allan, James Henderson Yule, John Alexander Mortimer, William Duncan Lawrie, William Sibbald Campbell, Norman Alexander Aylmer Hughes, Douglas Craig, Percy Charles Garrett, Leslie Wilson Evans, Reginald Norman Porritt, David Watt Torrance, Reginald Inglis Douglas, John Barron Scott, and James Finlay Alexander. Dated May 29th: Thomas Joseph Lydon, Frederick William Campbell, Andrew Louis Krogh, and Paul Ransome Browning. Dated May 31st: William Johnson Symes, Robert Brookes, and Michael Abdy Collins. Dated June 5th: Lieutenant Fraser Baillie Gurd, Canadian Army Medical Corps.

Frederick Hall to be temporary honorary Lieutenant whilst serving with the St. John Ambulance Brigade Hospital (dated June 10th).

Ralph Marsh de Mowbray to be temporary Lieutenant whilst serving with the British Red Cross Hospital, Netley (dated April 27th).

Arthur Conyears Inman is granted temporarily the honorary rank of Lieutenant (dated June 14th).

Special Reserve of Officers.

Royal Army Medical Corps.

The undermentioned Lieutenants (on probation) are confirmed in their rank:—Frank H. Kennedy, Norman B. Graham, James Lawson, Francis L. P. G. Bennett, Geoffrey B. Egerton, and Patrick A. Clements.

John Galloway Hendry (late Cadet Lance-Corporal, Glasgow University Contingent, Officers Training Corps) to be Lieutenant (on probation) (dated May 8th).

William McElrea Snodgrass (late Cadet Lance-Corporal, Dublin University Contingent, Officers Training Corps) to be Lieutenant (on probation) (dated May 30th).

TERRITORIAL FORCE.

Army Medical Service.

Major Ernest C. Freeman, Reserve of Officers, from Deputy Assistant Director of Medical Services, to be Assistant Director of Medical Services, East Anglian Division, with the rank of Colonel.

Lieutenant-Colonel David L. Hamilton, from 2nd Home Counties Field Ambulance, to be Deputy Assistant Director of Medical Services, Home Counties Division.

Royal Army Medical Corps.

Captain Charles A. Ballance, M.V.O., is seconded whilst holding a temporary commission in the Royal Army Medical Corps.

Captain John M. Fortescue-Brickdale is seconded for service with the Expeditionary Force.

3rd North Midland Field Ambulance: Lieutenant Crichton S. Lee is restored to the establishment.

4th London General Hospital: Captain Thomas C. English is seconded for service with the Expeditionary Force.

1st Northern General Hospital: James Ackworth Menzies to be Lieutenant.

2nd Northern General Hospital: Major James A. Coupland is seconded for service with the Expeditionary Force.

4th Northern General Hospital: Captain Frederick E. Withers is seconded for service with the Expeditionary Force.

2nd Southern General Hospital: Captain Ernest W. H. Groves is seconded for service with the Expeditionary Force.

Scottish Horse Mounted Brigade Field Ambulance: James Alexander Mathers (late Lieutenant, Scottish Horse Yeomanry) to be Captain (temporary).

2nd South Western Mounted Brigade Field Ambulance: John Hamilton Cumming to be Lieutenant.

2nd East Anglian Field Ambulance: Saville James Fielding to be Lieutenant.

2nd Northumbrian Field Ambulance: Christopher Rogers to be Lieutenant.

2nd Eastern General Hospital: Ernest Fryer Ballard to be Lieutenant.

2nd Home Counties Field Ambulance: Benjamin Allen Bull to be Lieutenant.

2nd London (City of London) General Hospital: Major Charters J. Symonds is seconded whilst holding a temporary commission in the Royal Army Medical Corps.

3rd Northumbrian Field Ambulance: John Gray (late Major, 6th Battalion, The Durham Light Infantry) to be Major (temporary).

Welsh Divisional Sanitary Section: Captain Robert Proudfoot, from Sanitary Service, to be Captain.

East Anglian Casualty Clearing Station: Major John H. Dauber to be Lieutenant-Colonel. Lieutenant Frederick W. Lewis (late Surgeon-Captain, South African Constabulary) to be temporary Captain.

1st East Anglian Field Ambulance: Captain William D. Watson, from Attached to Units other than Medical Units, to be Captain (temporary).

3rd Highland Field Ambulance: Lieutenant Edwin A. Bell resigns his commission.

3rd East Lancashire Field Ambulance: Wilfred Edwin Rothwell to be Lieutenant.

2nd West Lancashire Field Ambulance: William Francis Young to be Lieutenant.

1st Southern General Hospital: William Kirkpatrick to be Major, whose services will be available on mobilisation.

3rd Southern General Hospital: Captain Arthur G. Kewley, from 1st North Midland Field Ambulance, to be Captain, whose services will be available on mobilisation.

2nd Western General Hospital: Frank Chadwick to be Lieutenant.

Sanitary Service: Captain Alexander C. Farquharson, from Attached to Units other than Medical Units, to be Sanitary Officer, Northumbrian (Reserve) Division.

East Anglian Divisional Sanitary Section: Walter Francis Corfield (late Captain, 2nd London Sanitary Company) to be Captain.

West Lancashire Casualty Clearing Station: Cadet Theodore Howard Somervell, from University of London Contingent, Senior Division, Officers Training Corps, to be Lieutenant.

Attached to Units other than Medical Units.—Major Percival E. Barber is seconded for service with the R.A.M.C. To be Captains: Captain Lawder T. Whelan, from Sanitary Service, George Raymond (late Captain, 8th (Isle of Wight Rifles, "Princess Beatrice's") Battalion, The Hampshire Regiment), and Lieutenant Robert L. Routledge.

TERRITORIAL FORCE RESERVE.

Royal Army Medical Corps.

Colonel John R. I. Raywood (late Assistant Director of Medical Services, South Midland Division) to be Colonel.

VITAL STATISTICS.

VITAL STATISTICS OF LONDON DURING MAY, 1915.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious diseases, it appears that the number of persons reported to be suffering from one or other of the 10 diseases specified in the table was equal to an annual rate of 6·4 per 1000 of the population, estimated at 4,516,612 persons; in the three preceding months the rates were 7·4, 6·6, and 6·3 per 1000 respectively. The lowest rates last month were recorded in Hampstead, Stoke Newington, Bermondsey, Camberwell, and Lewisham; and the highest rates in Paddington, the City of Westminster, St. Marylebone, Stepney, Southwark, and Woolwich. One case of small-pox, which belonged to Stepney, was notified during the month. The prevalence of scarlet fever showed a slight increase as compared with the two preceding months; among the metropolitan boroughs this disease was proportionally most prevalent last month in Hammersmith, the City of Westminster, St. Marylebone, Finsbury, Stepney, and Woolwich. The Metropolitan Asylums Hospitals contained 2221 scarlet fever patients at the end of last month, against 2989, 2514, and 2339 at the end of the three preceding months; the weekly admissions averaged 283, against 324, 278, and 272 in the three preceding months. Diphtheria was less prevalent than it had been in any other recent month; the greatest proportional prevalence of this disease was recorded in St. Pancras, the City of London, Bethnal Green, Stepney, and Poplar. The number of diphtheria patients under treatment in the Metropolitan Asylums Hospitals, which had been 1562, 1362, and 1223 at the end of the three preceding months, had further declined to 1083 at the end of last month; the weekly admissions averaged 128, against 172, 142, and 136 in the three preceding months. The prevalence of enteric fever showed a marked decline last month; the 40 notified cases of this disease included 6 in Hackney, 4 each in St. Pancras, Bethnal Green, Lambeth, and Deptford, and 3 each in Stepney, Bermondsey, and Camberwell. The Metropolitan Asylums Hospitals contained 49 enteric fever patients at the end of last month, against 64, 46, and 60 at the end of the three preceding months; the weekly admissions averaged 6, against 13, 8, and 13 in the three preceding months. Erysipelas was proportionally most prevalent in Paddington, Shoreditch, Bethnal Green, Southwark, and Woolwich. The 32 cases of puerperal fever notified during the month included 4 each in Kensington and Southwark, 3 in Wandsworth, and 2 each in Chelsea, St. Pancras, Islington, Stepney, Lambeth, and Camberwell. The 87 cases of cerebro-spinal meningitis included 9 in Wandsworth, 8 in Kensington, 7 in Hammersmith, 6 in Shoreditch, and 5 each in Stepney, Battersea, and Camberwell. The 6 cases of poliomyelitis belonged respectively to Hampstead, St. Pancras, Islington, Bethnal Green, Wandsworth, and Woolwich.

The mortality statistics in the table relate to the deaths of persons actually belonging to the several boroughs, the deaths occurring in institutions having been distributed among the boroughs in which the deceased persons had previously resided; the death-rates from all causes are further corrected for variations in the sex and age constitutions of the several boroughs. During the four weeks ending May 29th the deaths of 5065 London residents were registered, equal to an annual rate of 14·6 per 1000; in the three preceding months the rates were 20·7, 21·2, and 19·6 per 1000 respectively. The death-rates last month ranged from 10·9 in Woolwich, 11·1 in Wandsworth, 11·3 in Paddington, 11·5 in Lewisham, and 11·7 in Hampstead, to 16·5 in Bethnal Green, 16·6 in Finsbury, 16·8 in Battersea, 18·2 in Shoreditch, 18·6 in Chelsea, 19·7 in Bermondsey, and 23·1 in the City of London. The 5065 deaths from all causes included 537 which were referred to the principal infectious diseases; of these, 269 resulted from measles, 20 from scarlet fever, 41 from diphtheria, 137 from whooping-cough, 10 from enteric fever, and 60 among children under 2 years of age from diarrhœa and enteritis. The lowest death-rates from these diseases in the aggregate were recorded in Kensington, Westminster, Hampstead, the City of London, Stepney, Lambeth, and Camberwell; and the highest rates in Chelsea, Islington, Shoreditch, Bethnal Green, Poplar, Bermondsey, and Battersea. The 269 deaths from measles were 119 in excess of the corrected average number; this disease was proportionally most fatal last month in Chelsea, Islington, Shoreditch, Bethnal Green, Poplar, Bermondsey, and Battersea. The 20 fatal cases of scarlet fever were 4 in excess of the average, and included 3 in Fulham, 3 in Islington, and 2 each in Hammersmith and Southwark. The 41 deaths from diphtheria

* Including membranous croup. † The death-rates are corrected for variations in sex and age constitution of the populations of the several boroughs, the population of England and Wales being taken as the standard.

were 9 above the average, and included 5 in Stepney, 4 in Lambeth, and 3 each in Hammersmith, Islington, Bethnal Green, and Wandsworth. The 137 deaths from whooping-cough were 22 above the corrected average; this disease was proportionally most fatal last month in Hackney, Finsbury, Bermondsey, Battersea, Deptford, and Greenwich. The 10 fatal cases of enteric fever were one in excess of the corrected average number, and included 4 in Hackney and 2 each in Southwark and Camberwell. The mortality from diarrhœa and enteritis among children under 2 years of age was proportionally greatest in Paddington, Hammersmith, St. Pancras, Islington, Shoreditch, Bethnal Green, and Southwark. In conclusion, it may be stated that the aggregate mortality in London last month from the principal infectious diseases was 48·1 per cent. above the average.

HEALTH OF ENGLISH TOWNS.

In the 96 English and Welsh towns with populations exceeding 50,000 persons at the last Census, 8092 births and 4297 deaths were registered during the week ended Saturday, June 19th. The annual rate of mortality in these towns, which had been 13·7, 13·9, and 13·5 per 1000 in the three preceding weeks, further fell in the week under notice to 12·4 per 1000 of their aggregate population, estimated at 18,136,180 persons at the middle of last year. During the first 11 weeks of the current quarter the mean annual death-rate in these towns averaged 15·7, against 15·8 per 1000 in the metropolis. The annual death-rate last week ranged from 4·1 in Hornsey, 6·2 in Leyton, 6·6 in Ealing, 7·0 in Walthamstow and in Warrington, and 7·5 in Willesden, to 18·4 in Barnsley, 19·3 in Blackpool, 21·0 in Middlesbrough, 21·6 in Gillingham, and 21·8 in West Bromwich.

The 4297 deaths from all causes were 400 fewer than the number in the previous week, and included 374 which were referred to the principal epidemic diseases, against 489 and 449 in the two preceding weeks. Of these 374 deaths, 162 resulted from measles, 68 from infantile diarrhœal diseases, 60 from whooping-cough, 45 from diphtheria, 29 from scarlet fever, and 10 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases did not exceed 1·1 per 1000, which is the lowest rate recorded in any week of the current year. The deaths attributed to measles, which had been 221, 239, and 215 in the three preceding weeks, further declined to 162 last week, and caused the highest annual death-rates of 2·3 in Sheffield, 2·9 in Barnsley, 4·4 in Walsall, 4·5 in Middlesbrough, and 5·3 in West Bromwich. The deaths of infants (under 2 years) referred to diarrhœa and enteritis, which had been 64, 75, and 90 in the three preceding weeks, fell to 68 last week, and included 12 in London and 4 each in West Ham, Liverpool, Salford, and Sheffield. The fatal cases of whooping-cough, which had declined from 137 to 75 in the four preceding weeks, further fell to 60 last week, of which 24 occurred in London and 3 each in Birmingham, Liverpool, St. Helens, Leeds, and Sheffield. The deaths attributed to diphtheria, which had been 31, 50, and 33 in the three preceding weeks, rose to 45 last week, and included 6 in London, 5 in Southampton, and 3 in Leyton. The deaths referred to scarlet fever, which had increased from 20 to 29 in the four preceding weeks, were again 29 last week, of which 9 were registered in London, 4 in Manchester, 3 in Salford, and 2 each in Edmonton and Liverpool. The fatal cases of enteric fever, which had been 11, 13, and 7 in the three preceding weeks, rose to 10 last week, and included 2 in London.

The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, which had been 2252, 2267, and 2336 at the end of the three preceding weeks, had further increased to 2373 on Saturday last; 330 new cases were admitted during the week, against 257, 327, and 330 in the three preceding weeks. These hospitals also contained on Saturday last 1048 cases of diphtheria, 77 of measles, 54 of enteric fever, and 12 of whooping-cough, but not one of small-pox. The 995 deaths from all causes in London were 108 below the number in the previous week, and corresponded to an annual death-rate of 11·5 per 1000. The deaths referred to diseases of the respiratory system, which had steadily declined from 469 to 165 in the nine preceding weeks, further fell to 153 in the week under notice, and were 10 below the number registered in the corresponding week of last year.

Of the 4297 deaths from all causes in the 96 towns, 215 resulted from various forms of violence, and 342 were the subject of coroners' inquests, while 1250 occurred in public institutions. The causes of 43, or 1·0 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in London and in its 14 suburban districts, in Sheffield, Leeds, Bristol, Hull, Newcastle-on-Tyne, and in 57 other smaller towns. Of the 43 uncertified causes, 8 were registered in Liverpool, 7 in Gillingham, 5 in Birmingham, 3 in Sunderland, and 2 each in Bootle, St. Helens, Darlington, South Shields, and Gateshead.

HEALTH OF SCOTCH TOWNS.

In the 16 largest Scotch towns, with an aggregate population estimated at 2,345,500 persons at the middle of this year, 1122 births and 704 deaths were registered during the week ended Saturday, June 19th. The annual rate of mortality in these towns, which had been 18·2, 18·9, and 17·9 per 1000 in the three preceding weeks, further declined to 15·7 per 1000 in the week under notice. During the first 11 weeks of the current quarter the mean annual death-rate in these towns averaged 18·5, against a corresponding rate of 15·7 per 1000 in the large English towns. Among the several towns the death-rate last week ranged from 7·0 in Clydebank, 7·6 in Falkirk, and 9·9 in Kilmarnock, to 18·6 in Ayr, 22·5 in Aberdeen, and 29·4 in Perth.

The 704 deaths from all causes were 102 fewer than the number in the previous week, and included 137 which were referred to the principal epidemic diseases, against numbers increasing from 90 to 148 in the four preceding weeks. Of these 137 deaths, 89 resulted from measles, 19 from whooping-cough, 17 from infantile diarrhœal diseases, 7 from diphtheria, and 5 from scarlet fever, but not one from enteric fever or from small-pox. The mean annual death-rate from these diseases was equal to 3·0, against 1·1 per 1000 in the large English towns. The deaths attributed to measles, which had been 72, 85, and 80 in the three preceding weeks, rose to 89 last week, and included 59 in Glasgow, 13 in Aberdeen, and 4 in Leith. The deaths referred to whooping-cough, which had been 43, 40, and 40 in the three perceding weeks, further declined to 19 last week, of which 8 occurred in Glasgow, 5 in Aberdeen, and 2 in Edinburgh. The fatal cases of diarrhœa and enteritis (among infants under 2 years), which had been 15, 10, and 12 in the three preceding weeks, further rose to 17 last week, and included 6 in Glasgow, 4 in Dundee, and 2 in Motherwell. The deaths attributed to diphtheria, which had been 10, 5, and 4 in the three preceding weeks, rose to 7 last week, of which 3 were registered in Glasgow and 2 in Paisley. The fatal cases of scarlet fever, which had been 5, 7, and 12 in the three preceding weeks, fell to 5 last week, and included 2 in Glasgow.

The deaths referred to diseases of the respiratory system, which had been 141, 145, and 126 in the three preceding weeks, further fell to 93 in the week under notice, but were 16 in excess of the number registered in the corresponding week of last year. The deaths from different forms of violence numbered 21, against 35 and 25 in the two preceding weeks.

HEALTH OF IRISH TOWNS.

In the 27 town districts of Ireland, with an aggregate population estimated at 1,212,380 persons at the middle of this year, 571 births and 331 deaths were registered during the week ended Saturday, June 19th. The annual rate of mortality in these towns, which had been 16·4, 17·0, and 15·4 per 1000 in the three preceding weeks, further fell to 14·2 per 1000 in the week under notice. During the first 11 weeks of the current quarter the mean annual death-rate in these towns averaged 18·8, against corresponding rates of 15·7 and 18·5 per 1000 in the English and Scotch towns respectively. The annual death-rate last week was equal to 16·4 in Dublin (against 11·5 in London and 17·0 in Glasgow), 13·2 in Belfast, 10·2 in Cork, 11·4 in Londonderry, 8·1 in Limerick, and 13·3 in Waterford, while in the 21 smaller towns the mean rate was 15·2 per 1000.

The 331 deaths from all causes were 26 fewer than the number in the previous week, and included 25 which were referred to the principal epidemic diseases, against 27 and 21 in the two preceding weeks. Of these 25 deaths, 7 resulted from infantile diarrhœal diseases, 6 each from measles and whooping-cough, 4 from scarlet fever, and 2 from diphtheria, but not one from enteric fever or from small-pox. The mean annual death-rate from these diseases was equal to 1·1, against corresponding death-rates of 1·1 and 3·0 per 1000 in the English and Scotch towns respectively. The deaths of infants (under 2 years) attributed to diarrhœa and enteritis, which had been 4, 12, and 2 in the three preceding weeks, rose to 7 last week, and comprised 5 in Dublin and 2 in Belfast. The deaths referred to measles, which had been 10, 3, and 7 in the three preceding weeks, were 6 last week, and included 5 in Belfast and 1 in Ballymena. The fatal cases of whooping-cough, which had been 3, 5, and 9 in the three preceding weeks, fell to 6 last week, of which 3 occurred in Dublin. The 4 deaths attributed to scarlet fever were slightly in excess of the average in the earlier weeks of the quarter, and included 2 in Belfast. The 2 fatal cases of diphtheria were registered in Dublin.

The deaths referred to diseases of the respiratory system, which had been 63, 56, and 64 in the three preceding weeks, fell to 57 in the week under notice. Of the 331 deaths from all causes, 103, or 31 per cent., occurred in public institutions, and 8 resulted from different forms of violence. The causes of 13, or 3·9 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest; in the 96 English towns the proportion of uncertified causes did not exceed 1·0 per cent.

Correspondence.

"Audi alteram partem."

THE POSITION OF THE ARMY CONSULTANTS.

To the Editor of THE LANCET.

SIR,—Questions in Parliament and correspondence in the papers have called attention to the position of the war consultants, whose appointment gave such universal satisfaction. Criticism naturally followed the discovery that those of the Navy had £5000 a year while the Army consultants had only the pay of their rank. No doubt there was a difficulty. While it would be possible to call the President of the Royal College of Physicians "Colonel," to address the President of the Royal College of Surgeons as "Admiral" would be Gilbertian! Pay, not rank, appears to have been the solution. This differential treatment seemed so unfair that it was hoped that the Army consultants would at once have been put on the same footing as their brethren in the Navy; but the tone of the questions in the House suggests a feeling that the pay of their rank is quite sufficient. I sincerely hope that this narrow view will not commend itself to Parliament. To the call of sacrifice in this crisis all willingly respond, and in the most distant parts of the Empire professional men have given up large remunerative practices to join the forces. But it is not fair to entail heavy losses upon a group of men selected for their special abilities. The earning life of a consultant is short—only 10 or 15 years of the "cakes and ale" stage. In a long expensive apprenticeship he gives to the poor from three to six hours a day of gratuitous service, in which he gains an experience of which the community at large reaps the benefit. We have no right to commandeer the brains of such men without a recompense proportionate to their talents and to their obligations. Many of them have fixed charges, domestic and educational, from three to four times in excess of the ordinary pay of a lieutenent-colonel in the army. Some, of course, can afford the sacrifice, but others, though making it willingly, cannot do so without injustice to their families. As absence of a year or two puts a consultant out of touch with his *clientèle*, these men have to face not only an immediate but a prospective loss of income.

Having seen the practice of several of the naval consultants, I can testify that the country is getting worth for its money, not only in the character of the work, but in the stimulus given to the environment in which it is done.

I am, Sir, yours faithfully,

Oxford, June 19th, 1915. WILLIAM OSLER.

THE WAVE-LENGTH OF VERY HARD X RAYS.

To the Editor of THE LANCET.

SIR,—THE LANCET of April 17th contained an article by one of us on the penetrating power of X rays from the Coolidge tube, and the question was raised as to how nearly the X rays may approach in penetrating power that of the hard gamma rays of radium. In this connexion it was stated that the very hard X rays emitted from the tube under a spark-gap of 30 cm.—i.e., about 130,000 volts—had a wave-length about three times that of the shortest gamma rays from radium that had been measured—viz., $0{\cdot}71 \times 10^{-9}$ cm. It was, however, stated that the observations did not preclude the possibility of still more penetrating X rays being produced, but that if harder X rays were present they did not contribute more than about 1 part in 50 to the effects associated with the heavily screened radiation.

At a lecture delivered at the Royal Institution on June 4th, Professor Sir E. Rutherford stated that in conjunction with Professor Barnes and Mr. H. Richardson he had for some time been engaged in an investigation upon the manner in which the wave-length of the X rays generated in the Coolidge tube depended upon the impressed voltage. He said that the hardest X rays which they had been able to produce were just about twice the wave-length of the hardest gamma rays from radium, the surprising fact being that there was only a small increase in the penetrating power of the rays when the voltage was increased from 125,000 to 145,000, and that no appreciable change resulted with a further increase to 175,000. This result refers to the rays of maximum penetrating power, and was obtained by such heavy screening of the beam of the X rays that its intensity was reduced to about one-thousandth part of its initial value.

Professor Rutherford drew attention to the importance which these facts have upon certain physical theories, and expressed the opinion that about 2,000,000 volts would probably be required to produce X rays of the same wave-length as the hardest gamma rays from radium. Considering the authority with which this opinion is invested we may assume that this often-discussed question is now settled and that a practical limit has been set to the hardness of X rays which are likely, at any rate in the near future, to be available for clinical purposes. It is of immediate interest in this connexion to know the proportion that these rays of very short wave-length bear to the whole radiation coming from the tube; from the fact that they were only revealed when very heavy screening was resorted to, it may be inferred that they form a very small percentage of the whole radiation. With an improved yield in the amount of radiation from the Coolidge tube, it remains to be seen whether they will be sufficient in quantity for therapeutic purposes. It may be stated that an approximately homogeneous beam of very hard X rays of wave-length $2{\cdot}1 \times 10^{-9}$ cm. is obtained from the Coolidge tube under a spark-gap of 30 cm. (points), the rays being screened by 7 mm. of aluminium. Such radiation has been in use in the electro-therapeutic department of the Middlesex Hospital during the last two months.

We are, Sir, yours faithfully,

C. R. C. LYSTER,
Middlesex Hospital, W., June 15th, 1915. SIDNEY RUSS.

THE UNIVERSITY OF MELBOURNE: PRACTICAL LOYALTY.

To the Editor of THE LANCET.

SIR,—I am instructed by the Chancellor of the University of Melbourne to state, for the information of your numerous readers, that at a meeting of the teaching staffs of the University and affiliated colleges held on April 21st the following resolutions were passed *nemine contradicente*:—

1. That during the continuance of the war the members of the staff of the University and affiliated colleges pledge

themselves to abstain from the use of alcohol, except under medical advice.

2. That the committee to be appointed at this meeting be requested to consider the question whether a University rifle club can be formed with advantage, and whether any other action can be taken in substitution for such a club, or in addition to it; and, further, that the members of the teaching staff of the University and the affiliated colleges pledge themselves to encourage volunteering among the members of the University by such means as may be approved by the committee to be formed.

3. Though many special services have already been performed by officers of the University at the invitation of Ministers, it is desirable to make it more definitely understood that such services are available, and therefore that the council be asked to approach the Federal and State Governments with the suggestion that the members of the staff of the University would be willing to offer their services, as far as compatible with the continuance of University work, to aid or supplement wherever possible the work of the scientific, technical, or professional branches of the Government departments during the war on any matters connected with Imperial defence in which their assistance may be useful.

4. That this meeting is of opinion that public lectures under the auspices of the University should be given on the subject of the war, its causes, its importance to Australia, and the political and other problems which will arise from it; and that the council be requested to give its support to this course.

5. That the administration of the above resolutions be placed in the hands of a representative committee, with power to appoint special committees.

Concerning the first resolution I am further instructed to state that, whilst every member of the staffs was informed of the meeting, which was in consequence largely attended, no attempt has been made to force the resolution upon those who were unable to attend.

I am, Sir, yours faithfully,
RICHARD J. A. BERRY,
Honorary Secretary, Executive University War Committee.
Melbourne, May 8th, 1915.

THE WAR AND THE MEDICAL PERSONNEL.

To the Editor of THE LANCET.

SIR,—Mr. Tennant's statement in Parliament that at present no more surgeons are needed either at home or abroad gives us time to ascertain the best means of supplying the large number which will be required shortly. In the *Times* "History of the War," No. 41, p. 74, the statement is made that after nine months of war there is still a shortage of 2000 surgeons. This is about the number whose services, according to Mr. Tennant, had been declined. If there was a shortage, why were the offers of 1900 applicants rejected? If there was no shortage, why does the writer of history say there was? The question is, has the writer of history knowledge of facts and reliable figures of which Mr. Tennant is ignorant? The answer is in the negative. For the credit of the profession and of history let it be put on record that there was not a shortage of surgeons after nine months of war; but, even if there were, it was from no lack of offers.

With your permission, I propose briefly to review the present and future situation. A good deal of solicitude has been expressed, by those not conversant with general practice, lest there should be a future shortage of doctors. The truth is that through the passing of the Insurance Act, the same population will not support anything like the same number of medical men; and it would probably be a good thing for the profession and for the public, if no students, of either sex, entered at the schools of medicine for the next five years. In addition most patients will be financially crippled by the war and doctors will be the first to suffer and the last to be paid. In the present situation, it is certain every medical man would offer his services if our wounded wanted him, provided that he had some guarantee that his practice would be safeguarded in his absence. The only thing clear from the various schemes advanced in the interest of the absentee is that there will be a good deal of friction or even litigation on his return.

Now, Sir, the one authority capable of reducing this friction to a minimum is the General Medical Council. The service of the Council would be *pro patria*, and if undertaken would induce quite enough medical men to offer themselves for the succour of our sick and wounded. The expense might well be met by a Government grant.

If the General Medical Council issued a short scheme equitable to the absentee and to the man who carried on the practice, and at the same time agreed to mediate in case of dispute, there would be an ample supply of military surgeons. No other body has the requisite moral force behind it. At present certain reserve battalions of Territorials seem to be short of surgeons, but this is work that can be done by civilian doctors in the districts where the troops are stationed.

The pay of the Territorial surgeon is a strange anomaly. In the past, in many cases, he has given money and much time, with his only reward a good-natured derision. He now gets less than two-thirds the pay of any recently qualified young man who likes to join Kitchener's army. Mr. Harold Baker stated in the House that there is no hardship, since the bargain was made with open eyes. The inference is that the penalty for patriotism is 9*s*. a day. History will do more justice to the Territorial, for it will say he saved Calais, perhaps England.—I am, Sir, yours faithfully,

Formby, June 21st, 1915. ARTHUR C. WILSON.

"MILITARY HONOURS."

To the Editor of THE LANCET.

SIR,—With regard to the letter appearing under this title in your issue of June 12th may I suggest to Mr. W. H. Clayton-Greene that perhaps time might have been saved if instead of giving his certificate to the registrar he had first of all written to the coroner stating the circumstances of the man's death, and at the same time intimating his willingness to give a certificate of death should the coroner approve. By the same post the War Office could be notified of the death and requested to take the funeral in hand. There is a point here, of course, which should not be overlooked, that some coroners prefer all communications to be made through the police or through their own officer. Then, again, it was natural that the coroner should want to know of any relative for the purpose of identification. The War Office then having been apprised that a military funeral had to be provided could have forthwith ordered a coffin from the undertaker, and the latter would begin his work at once, probably the day after death. It would surely also be the duty of the undertaker to arrange all the details of the funeral, including the services of the clergyman and the time and place, and in this connexion he would probably like to consult with the sister mentioned in Mr. Clayton-Greene's letter. Meanwhile the coroner is considering whether he can allow Mr. Clayton-Greene to give a certificate of death in the usual way. He decides yes, and straight away says so. Mr. Clayton-Greene gives his certificate, all for nothing, on the statutory form: the sister, or the nurse who witnessed the death, or the undertaker conveys the same to the registrar of the district or subdistrict. Finally, the registrar makes a copy in his register and also makes a duplicate copy for the undertaker, which is handed to the clergyman at the graveside.—I am, Sir, yours faithfully,

Weston-super-Mare, June 17th, 1915. R. A. EARLE.

"GROWING PAINS" AND RHEUMATISM?

To the Editor of THE LANCET.

SIR,—I think Dr. M. H. Williams, in the interesting paper on Rheumatism in Children appearing in your issue of June 19th, rather overstates the case when she advances the opinion that aching of the legs in children is almost always due to rheumatism —prefacing this remark by stating that by rheumatism she means infection by a specific organism, and following it up by saying that the riddle of treatment is unanswerable. There is no doubt but that her words contain much truth. Dr. Williams, however, makes no mention of what in my opinion is (in this locality at any rate) the commonest cause of "growing pains," and that is the absorption of toxins through adenoid vegetations. It is quite extraordinarily common in my experience to find children with a tendency to fidgets, a constantly raised temperature up to 99·5–100° F., and a muffling of the first cardiac sound in which the whole state can be completely altered by removal of adenoids. I particularly wish to state I do not mean obvious adenoid cases with obstructive signs. Careful examination will almost certainly show a few soft and slightly enlarged cervical glands, but with this exception the signs are general and not local. Treatment by salicylic acid compounds causes no more than a temporary lowering of temperature, and in the cases I have in mind the tuberculin skin tests are negative—both human and bovine.

I have no means of knowing whether the toxin absorbed is that of the specific organism of Poynton and Paine; but if it is, the riddle of treatment can be very readily solved, which is certainly not the experience of most of us with that organism or one closely allied to it.

I am, Sir, yours faithfully,

Chiswick, W., June 21st, 1915. H. O. BUTLER.

THE POSITION OF SURGEONS TO TRANSPORTS.

To the Editor of THE LANCET.

SIR,—Various companies are advertising for ships' surgeons and offering the sum of £15 to £20 per month as salary to those who act in this capacity. One ship was chartered for transport work and the company it belonged to could not procure a surgeon, although they were prepared to offer £500 per annum. Eventually the company arranged with a military medical officer to act as ship's surgeon at the rate of £1 per day. Personally I have "signed on" at the rate of £15 per month, and so, as I am in distant parts, do not see much chance of a remedy. Further, there is, I believe, a war bonus paid by the Admiralty to every member of the crew for war risks; but so far I have been unable to ascertain from this company, a well-known line, whether any proportion is to be awarded to the surgeon.

Besides the important matter of pay, intending surgeons in the Mercantile Marine and passenger ships ought to investigate accommodation provided for them. I berth next to the cook, the barman, and the head waiter in the "slums" of the ship. There is plenty of other work for medical men to do now, and the present is a good opportunity of securing better conditions all round for the doctor in the Mercantile Marine.

I am, Sir, yours faithfully,

June 23rd, 1915. "M."

PROLONGED ANÆSTHESIA.

To the Editor of THE LANCET.

SIR,—Which is the longest period over which an anæsthetic has been known to be given for one operation? I had just recently a case of a man, aged 82, operated upon for malignant growth of the pelvic colon, which took exactly four hours, and therefore the anæsthetic lasted just a few minutes over this time. The patient stood the anæsthetic very well, did not vomit after it, and six hours after the operation was finished he was able to converse with his friends.

The anæsthetic I used throughout the operation was ether, with the exception of a few minutes at the beginning, when chloroform was used. No morphia or atropine was used beforehand, and it is extraordinary that he has not been troubled by any catarrh of the lungs or excess of secretion.

I am, Sir, yours faithfully,

June 19th, 1915. M.B., B.S.

Medical News.

VICTORIA UNIVERSITY OF MANCHESTER.—The following candidates have been approved for the degree of M.D.:—

J. S. B. Stopford (awarded gold medal) and G. C. Mort.

ROYAL MEDICAL BENEVOLENT FUND.—At the last meeting of the committee 28 cases received grants amounting to £294, and two applicants were elected to vacant annuities of £20 each. The following is a summary of the cases relieved:—

Daughter, aged 47, of M.R.C.S. Eng. who practised at Clifton, Bristol. Applicant completely incapacitated owing to complications following operation for hernia. At present in a convalescent home. Lost use of both legs. Prior to illness earned a living by acting as children's nurse. Voted £10 in two instalments.—Daughter, aged 63, of L.R.C.S. Glasg. who practised at Liverpool. For a number of years acted as matron to a private mental home, but has not been able to save. A younger matron is now required, and applicant must try to obtain other work and finds it difficult at her age. Voted £12 in 12 instalments and referred to the Guild.—Widow, aged 34, of L.S.A. Lond. who died in January of this year, and had acted as locum-tenent in various places. Left the applicant totally unprovided for with three children ages 12 to 17 years. Hopes to obtain some employment. Voted £10 in two instalments.—Widow, aged 73, of L.S.A. Lond. who practised at Bermondsey, and died in 1887. Until the outbreak of war was able to make a living by taking in boarders at her house on the South Coast. All the August and autumn bookings last year were cancelled, and has had to close up the house temporarily. Lives in own house, which is heavily mortgaged. Voted £15.—M.R.C.S. Eng., aged 58, who had practised in the Midlands, and now suffering from total paralysis of the right side and unable to speak or write. Only income a pension of £30 per annum, and a little from the sale of his practice. His wife has to devote all her attention to him, and the three children are unable to help financially. Voted £2, and referred to the Guild for report.—Widow, aged 70, of M.D. St. And. who practised in Pall Mall, S.W., but was incapacitated for some years before death in May of this year, and was a pensioner of the Fund, and received assistance from another charity. Applicant left entirely unprovided for. Voted £2, and referred to the Guild for report.—Daughter, aged 66, of M.R.C.S. Eng. who practised in London. Has earned a living as a teacher of languages, but cannot obtain pupils at present. Lives with two sisters, who try to earn a living by keeping a boarding-house, but not successfully. One of the sisters also receiving a grant from the Fund. Voted £12 in 12 instalments and referred to the Guild for report.—Widow, aged 54, of M.R.C.S. Eng. who died in 1897 and practised at Stockton-on-Tees. Left totally unprovided for with two young children to educate and keep. Has earned a little by needlework and has acted as caretaker. Eyesight now very bad. Daughter now earning a little and son has joined the army. Previous help 11 times, £97. Voted £9 in 12 instalments.—M.R.C.S. Eng., aged 48, who practised at Aysgarth, and as surgeon to a steamship company, which took him abroad, where he contracted sunstroke with very bad effects, and is now totally incapable of doing anything. Lives with an aunt who has barely sufficient for her own needs. Previous help £10. Voted £10 in two instalments.—Widow, aged 52, of L.R.C.P. & S. Edin. who practised at New Quay. Health very indifferent and has recently had an accident which has incapacitated her from doing any work. Has two sons, sailors, but they are only able to help very slightly. Relieved 12 times, £125. Voted £12 in 12 instalments.—Widow, aged 69, of M.R.C.S. Eng. and L.S.A. Lond. who died in 1887, and practised at Heathfield, Sussex. Used to earn a bare living by taking in boarders, but is now suffering from rheumatoid arthritis, and has had to give up her home, and is now in a home for gentlewomen, but requires money for food. Previous help seven times, £75. Voted £12 in 12 instalments.—Widow, aged 57, of M.R.C.S. Eng. who practised at Enfield, and died in 1905. Applicant has indifferent health and daughter is suffering from spinal diseases. Only income a little help from friends. Relieved four times, £40. Voted £5.—M.D. Aberd., aged 62, who practised at Walsall Suffering from rheumatoid arthritis since 1881. Has four children ages 4 to 16 years. Has three small pensions from other charities. Previous help seven times, £63. Voted £12 in 12 instalments.—Daughter, aged 60, of L.F.P.S. Glasg. who practised at Mauchline. Health very bad and unable to undertake any definite work. Only certain income a pension from another charity of £12 per annum. Relieved eight times, £80. Voted £12 in 12 instalments.—Widow, aged 50, of L.R.C.P. & S. Edin. who practised in Jamaica. At husband's death in 1891 was left with three daughters and totally unprovided for. Health has been very bad, and applicant has just been elected an out-patient pensioner of a home for incurables. Lives with married daughter, who cannot afford to keep her. Relieved seven times, £84. Voted £12 in 12 instalments.—Widow, aged 63, of M.D. Glasg., who died in 1908 and practised at Glasgow. Applicant has tried to make a living by taking in boarders, but latterly has not been successful, and sister who helped in the house is now bedridden with paralysis. Relieved once, £12. Voted £12 in 12 instalments.—Widow, aged 49, of L.S.A. Lond. who practised at Leicester and died in 1910. Applicant was left with four children, whose ages are now 11–21. The two eldest daughters are clerks and pay over their wages to their mother, but this is not sufficient to keep the house. The applicant tries to supplement her income by doing a little needlework. Relieved three times, £34. Voted £12 in 12 instalments.—Daughter, aged 76, of M.R.C.S. Eng. who practised at Hackney. Owing to great age the applicant is unable to undertake any work. Three brothers who used to help her have recently died. Only income £33 per annum. Relieved three times £36. Voted £15 in 12 instalments.—Widow, aged 66, of L.S.A. Lond. who practised at Ipswich. Since the death of her husband in 1901 has endeavoured to make a living by letting apartments, but not very successfully. Children only able to help very little. Relieved 13 times, £140. Voted £12 in 12 instalments.—Daughter, aged 51, of M.R.C.S. Eng. who practised at Box, Wilts. Applicant is a permanent invalid and unable to work. Lives with sister who earns a little and has a grant from the Fund. Relieved three times, £36. Voted £12 in 12 instalments.—Daughter, aged 47, of M.R.C.S. Eng. who practised in India. Has endeavoured to earn a living by taking in boarders, but cannot make ends meet. Has just removed into the country and pays less rent, and hopes in the future to manage without troubling the Fund. Relieved four times, £42. Voted £12 in 12 instalments.—Widow, aged 44, of L.R.C.P. & S. Edin. who practised in South Wales and died in 1903. Left unprovided for at husband's death with two daughters, the eldest of whom is studying as a teacher of domestic economy and hopes to earn a little soon. Applicant earns a little as a maternity nurse Relieved nine times, £65. Voted £5.—Widow, aged 35, of M.R.C.S. Eng. who practised at Bow, E., and died in 1912. Applicant has one child, and being a nurse by profession endeavours to make a living by taking in mental cases in her house in the suburbs, but finds it difficult to make ends meet. Wants assistance towards the education of her son. The case was referred to the Guild, and a certain sum allocated subject to the report being satisfactory.—Widow, aged 60, of M.D. Glasg. who practised at Birkenhead and other places. Left unprovided for at husband's death. Three daughters, ages 31–33 years. The two eldest earning a little, but the youngest is a confirmed invalid. Applicant suffering from neuritis. Relieved six times, £96. Voted £6 in 12 instalments.—Daughters, ages 48 and 56, of M.D. Aberd. who practised in Yorkshire. Both are unable to work owing to illness. Only income £20 each per annum. Relieved twice, £20. Voted an immediate grant of £1, and referred to the Guild for report.—Daughter, aged 60, of M.D. Edin. who practised in London. Health very indifferent, and only income about £4 per annum from needlework. Lives with a sister who is an invalid. Relieved seven times, £49. Voted £12 in 12 instalments.—Widow, aged 59, of L.R.C.P. & S. Edin. who practised at Balham, and died in 1913. Lives in own house and takes in boarders when she can get them, but cannot get sufficient to make it pay. Relieved twice, £14. Voted £12 in 12 instalments.—Daughter, aged 67, of M.R.C.S. Eng. who practised in Lancashire. In consequence of ill-health and age unable to work. Only income £30 per annum from another charity, and has just been elected to an unfurnished home. Wants help for furnishing. The Liverpool Branch of the Guild are assisting. Relieved four times, £60. Voted £10 at the direction of the Guild at Liverpool.

The claims of the Fund are steadily increasing, largely in consequence of the war, and though the ordinary subscriptions remain at much the same level, there is a constantly increasing adverse balance. At the last meeting the committee was faced with an overdrawn account of £92, which was increased by the £294 then spent in grants to a total deficit of £386. To meet this the committee has had to draw upon its limited reserves, and unless support be rapidly forthcoming its work will have to be curtailed. Subscriptions may be sent to the honorary treasurer, Dr. Samuel West, 11, Chandos-street, Cavendish-square, London, W.

CENTRAL MIDWIVES BOARD.—A meeting of the Central Midwives Board was held at Caxton House, Westminster, on June 17th, with Sir Francis H. Champneys in the chair. A letter was considered from the town clerk of Southend-on-Sea asking the Board for suggestions as to a method by which the disability experienced by lying-in women in obtaining medical aid in response to requests made by certified midwives under the rules of the Board may be dealt with. The Board directed that the town clerk be informed that the Board has ever since its establishment urged the Privy Council to promote legislation for dealing with the question of the payment of medical practitioners called in at the instance of midwives in accordance with the rules of the Central Midwives Board; as the Board's opinion has been asked they may say that they think that if the guardians could see their way to pay the prescribed fees to the practitioner duly called in in the first instance and to recover the fees from the patient where the patient is able to pay, it would greatly conduce to the welfare of the poor mothers of the community. A letter was considered from the medical officer of health of Chester asking the Board's opinion as to the propriety of a midwife recommending hand-feeding. The Board directed that the medical officer be informed that the question as put is too vague to admit of a definite reply. If such a reply is desired particulars will have to be furnished in a definite case or in definite cases.

The following letter was read from the honorary secretary of the Midwives Institute as to the decision of the High Court in the case of a Midwife *v.* Central Midwives Board:—"The Midwives Institute has noted with great regret the reversal by the High Court of the decision of the Central Midwives Board in the case of a midwife who was struck off the roll. We understand that the charge was one of immorality, and that the reversal of the Board's decision was made in consequence of some technical omission. The Midwives Institute feels that the result of this case is liable to very serious misconstruction by the general public. I have therefore been requested to forward to your Board the following resolution: 'The Midwives Institute respectfully ask the Central Midwives Board to make a pronouncement, which can be reported in the press, that in spite of the High Court's reversal of the Central Midwives Board's decision in a recent case the Board will, as it has heretofore done, continue to support the *moral* as well as the *professional* status of practising midwives.'" The Board decided that the honorary secretary of the Midwives Institute be informed that the decision of the High Court in the case of a Midwife *v.* Central Midwives Board, although reversing the decision of the Central Midwives Board to remove the name of the midwife from the roll, confirms the Board in their position as the authority which determined what is and what is not misconduct in a midwife, and decided that misconduct is not to be limited to misconduct in a professional sense; the Board has held that conduct which, before enrolment would render it impossible to certify that a candidate was "of good moral character" renders her, after enrolment, liable to be removed from the roll for "misconduct."

DEATH OF A SHEFFIELD MEDICAL MAN.—Mr. Herbert Leonard Hudson, L.R.C.P. Irel., died at his residence in Sheffield on June 11th in his fifty-eighth year. He was born in Calcutta and at an early age came to England with his parents, who settled in Hull. About the year 1887 he began medical practice in Sheffield, where he became popular with all classes. He leaves a widow, a son who is studying medicine at Sheffield University, and a married daughter.

WESTERN COUNTIES INSTITUTION FOR MENTAL DEFECTIVES.—At the annual meeting of the subscribers to the Western Counties Institution, held recently at Starcross, under the presidency of the Earl of Devon, it was stated that during the 50 years the institution had been in existence 1451 children had been admitted. The first annual report showed that 12 children were admitted at an expenditure of £965. Last year 347 cases were treated, the daily average number being 303, and the annual expenditure was £11,077.

THE HERITAGE COLONY.—H.R.H. Princess Louise, Duchess of Argyll, will inspect the military wards named after her at the Heritage Colony for Boys at Chailey on Thursday next, July 1st.

BRITISH SYMPATHY WITH ITALY.—The British residents and visitors in Rome propose that their sympathy with their gallant ally, Italy, should take the form of assistance to the wounded Italian soldiers by the provision of complete equipment for one or more wards, according to the funds raised, in one of the hospitals which are now being prepared. The Medical Inspector-General, Lieutenant-General Luigi Ferrero di Cavallerleone, has signified his cordial approval of this suggestion, and will be happy to reserve a special ward, or wards, to be equipped by British aid. Subscriptions, however small, will be gratefully received by Dr. George Sandison Brock, M.D., 6, Corso d'Italia, Rome, who will also gladly undertake the application of the sum collected to its intended purpose. If not sent to him personally subscriptions should be addressed to Mr. E. J. Wallman, care of Messrs. Cook and Son, 54, Piazza Termini, Rome, who will duly acknowledge their receipt.

MEDICINE AND THE CIVIL LIST.—Among the Civil List pensions granted during the year ended March 31st, 1915, are one of £80 to Mrs. J. E. Baker, in consideration of the services of her husband, the late Dr. Hugh Baker, in the investigation and treatment of sleeping sickness in Africa; one of £60 to Mrs. Constance Emily Burch, in consideration of the value of the researches of her husband, the late Dr. George James Burch, F.R.S., in physics and physiology; one of £50 each to Mr. William Grenfell Wallace, and Miss Violet Wallace, in consideration of the scientific work of their father, the late Dr. Alfred Russel Wallace, O.M.; and one of £150 to Dr. Charlton Bastian, F.R.S., in consideration of his services to science.

THE LATE DR. JAMES STEWART ORCHARD.—The death of Dr. James S. Orchard took place at his residence, West Didsbury, Manchester, on June 18th. Up to the end of 1914 he was the medical superintendent of the Withington Hospital, Manchester, a position which he had held since 1879. Dr. Orchard was at one time medical officer of the Salford Union Infirmary.

THE COLONIAL NURSING ASSOCIATION.—The nineteenth annual report of the executive committee of this association for the year ending March 31st, 1915, has just been issued. The object of the association is to provide trained nurses for hospital and private work in the British colonies and dependencies, and among other British communities abroad, and in this work there has been a steady advance during the year under notice. Although the outbreak of war has very considerably increased the difficulties of filling colonial posts, the number of nurses at work during the past year has been 338, this being in excess of any previous year. Of this number, 93 have been employed as private nurses, 17 in hospitals not under Government, 21 under the Government of Western Australia, and 207 in Government service in the Crown colonies.

ROYAL VICTORIA INFIRMARY, NEWCASTLE-ON-TYNE.—The quarterly court of governors of this institution was held on June 17th under the chairmanship of Alderman W. J. Sanderson. The financial statement showed that the total expenditure for the four months ending April 30th, including extraordinary expenditure, was £15,043, while the total income, including legacies, was £13,533. Since the outbreak of the war 2300 sick and wounded soldiers have been treated in the wards of the Royal Victoria Infirmary, and in the out-patient department more than 30,000 applicants have been inoculated against typhoid.

PRESENTATION OF THE LONG SERVICE MEDAL TO MAJOR JAMES PHILIP STEPHENS WARD, R.A.M.C. (T.).—At the Plymouth Citadel on June 13th Major Ward, who is attached to the Devon Royal Garrison Artillery, was presented with the long service medal by Major-General A. P. Penton, C.V.O., C.B., Garrison Commander.

THE Lecomte triennial prize, £2000 in value, has been awarded by the Paris Académie des Sciences to Sir Almroth Wright.

MR. A. H. Tubby has been elected an Honorary Member with medal of the First Class of the Società Fisico-Chimica Italiana.

A MEDICAL BARRISTER.—Mr. J. Beard, medical officer of health of the city of Carlisle, has been called to the Bar at Gray's Inn.

The War.

THE CASUALTY LIST.

SINCE our last issue the following names of medical men are in the lists of those who have fallen in the war from wounds or gas-poisoning:—

Died of Wounds: Major J. C. Taylor, R.A.M.C. (T.F.), attached 4th Battalion Royal Scots Fusiliers (T.F.).

Lieutenant E. A. Wright, R.A.M.C. (only son of Mr. A. Wright, M.R.C.S., L.S.A., of Romford), from septic poisoning contracted in attending on patients.

Wounded: Lieutenant W. J. Maloney, attached 4th Worcester Regiment, Major O. R. Ennion, East Anglian Field Ambulance (T.F.), Captain C. C. Fitzgerald, attached 7th Lancashire Fusiliers (T.F.), Lieutenant D. Bell, and Lieutenant G. S. Deane (*gas-poisoning*), all of the R.A.M.C.; Lieutenant H. M. Gauntlett, attached 4th Oxford and Bucks Light Infantry, Lieutenant W. W. Adamson, 2nd West Riding Field Ambulance, both of R.A.M.C. (T.F.).

Prisoner: Lieutenant J. M. Gillespie, R.A.M.C. (previously reported missing).

DEATHS AMONG THE SONS OF MEDICAL MEN.

The following have to be added to the sons of medical men who have fallen in the war:—Second Lieutenant W. P. Heffernan, second son of Mr. W. K. Heffernan, L.R.C.P. & S. Irel., J.P., of Killenaule; Second Lieutenant G. M. Hume, third son of Dr. G. H. Hume, late of Newcastle-on-Tyne; Lieutenant W. H. Fox, elder son of Dr. G. M. Fox, of Walsall; Lieutenant C. C. A. Ratcliff-Gaylard, elder son of Dr. J. Ratcliff-Gaylard, of Birkenhead.

Flight Sub-Lieutenant Warneford, V.C., may also be included here, for he was the son of Mrs. Corkery, wife of Lieut.-Colonel Corkery, R.A.M.C.

MENTIONED IN DESPATCHES.

The following officers connected with the medical profession and occupying the indicated positions with our army are recommended in Sir John French's despatch, dated May 31st and issued from the War Office this week, "for gallant and distinguished service in the field." Alas, several of them are no longer with us.

THE HONOURS LIST.

Following Sir John French's despatch, dated May 31st, and the above list of names brought forward by the Commander-in-Chief, the King has approved of a long list of rewards for "services rendered in connexion with operations in the field." The following are the medical officers promoted or appointed to Orders:—

General Headquarters Staff, &c.

Brevet-Colonels.—Lieut.-Col. M. H. G. Fell and Lieut.-Col. H. Ensor.

C.B.—Lieut.-Col. W. W. O. Beveridge, D.S.O., Col. H. Carr, Col. R. J. Geddes, D.S.O., and Col. W. T. Swan.

C.M.G.—Lieut.-Col. S. L. Cummins, Lieut.-Col. P. Evans, Lieut.-Col. H. B. Fawcus, and Lieut.-Col. A. L. A. Webb.

D.S.O.—Major F. S. Irvine and Surg.-Major B. Pares.

Military Cross.—Capt. P. Dwyer.

Medical Service and R.A.M.C.

Brevet Lieut.-Colonel.—Major J. S. Bostock.

C.B.—Col. (temp.) F. F. Burghard, Col. (temp.) Sir W. P. Herringham, Col. J. Meek, Col. S. G. Moores, Col. S. Westcott, C.M.G., and Col. (temp.) Sir A. E. Wright.

C.M.G.—Lt.-Col. G. S. Crawford, Lt.-Col. T. H. J. C. Goodwin, D.S.O., Major J. F. Martin, Lt.-Col. J. C. B. Statham, Lt.-Col. H. S. Thurston, Lt.-Col. A. E. L. Wear, and Major Sir E. S. Worthington, M.V.O.

D.S.O.—Capt. C. G. Browne, Capt. H. St. M. Carter, Major R. V. Cowey, Capt. T. J. Crean, V.C., Major T. E. Fielding, Capt. R. Gale, Capt. P. A. Lloyd-Jones, Capt. O. W. McSheehy, Lieut.-Col. J. Poe, and Capt. (temp.) O. Richards.

Military Cross.—Lieut. W. McM. Chesney, Lieut. D. D. Craig, Capt. W. Darling, Capt. G. F. Dawson, Lieut. (temp.) F. T. Hill, Capt. H. L. Howell, Lieut. (temp.) P. W. James, Lieut. (temp.) H. G. Janion, Capt. J. B. Jones, Capt. E. J. Kavanagh, Lieut. (temp.) W. H. Lister, Lieut. (temp.) I. C. Maclean, Lieut. R. A. Preston, Lieut. (temp.) P. Smith, Capt. J. W. C. Stubbs, Capt. H. F. Vellacott, Capt. N. T. Whitehead, and Capt. H. G. Winter.

Staff, 1st Canadian Division.

C.B.—Lieut.-Col. (temp. Col.) G. La F. Foster.

D.S.O.—Capt. (temp. Major) H. A. Chisholm.

Canadian Army Medical Corps.

C.M.G.—Lieut.-Col. F. S. L. Ford.

D.S.O.—Capt. T. H. McKillip.

Military Cross.—Lieut. A. K. Haywood.

Indian Medical Service.

C.M.G.—Lieut.-Col, C. H. Bowle-Evans and Lieut.-Col. F. Wall.

D.S.O.—Capt. John Taylor.

Military Cross.—Capt. J. S. O'Neill and Second-class Sub-Asst. Surg. Ramkrishna Ganpat Shinde.

Brevet-Colonel.—Lieut.-Col. W. W. White.

THE VICTORIA CROSS.

The Victoria Cross has been awarded to Captain F. A. C. Scrimger, Canadian Army Medical Service, Medical Officer, 14th Battalion, Royal Montreal Regiment, for directing, on April 25th, near Ypres, under heavy fire, the removal of the wounded and himself carrying a severely wounded officer out of a stable to a place of greater safety, and remaining with him under fire till help could be obtained. During the very heavy fighting between April 22nd and 25th Captain Scrimger displayed continuously day and night the greatest devotion to duty among the wounded at the front.

COMPENSATIONS AND PENSIONS FOR MILITARY MEDICAL OFFICERS.

We stated last week, in response to many inquiries, that the compensation for injury and pensions for widows and children and other compassionate allowances during the present war were the same for Special Reserve, Territorial, and temporarily commissioned officers as for permanent officers of the Royal Army Medical Corps. We now put them before our readers in tabular form:—

Pensions and Gratuities to Wounded Officers (under the rank of Colonel) of the Regular Army, the Special Reserve of Officers, and the Territorial Force, and to Officers holding only Temporary Commissions for the Purposes of the Present War.

—	Wounds and injuries received in action or on flying duty.		Wounds and injuries received on duty otherwise than in action or on flying duty.	
Rank of officer (i.e., permanent rank unless the officer holds only temporary rank).	1 Gratuity for "very severe" injury, to be followed by pension (col. 2) if effects are permanent.	2 Pension for "very severe and permanent" injury following gratuity (col. 1).	3 Gratuity for "severe and and permanent" injury (no pension).	4 Pension for "very serious and permanent" injury (no gratuity).
	*	†	*	†
Lieutenant-Colonel ...	From £112 10*s.* to £450.	From £150 to £300 a year.	From £112 10*s.* to £450.	From £120 to £250 a year.
Major... ...	From £75 to £300.	From £100 to £200 a year.	From £75 to £300.	From £80 to £150 a year.
Captain ...	From £52 10*s.* to £250.	From £50 to £100 a year.	From £62 10*s.* to £250.	From £40 to £75 a year.
Lieutenant	From £35 to £140.	From £35 to £70 a year.	From £35 to £140.	From £30 to £50 a year.
Second Lieutenant	From £25 to £100.	From £35 to £70 a year.	From £25 to £100.	From £30 to £50 a year.

* The amount of gratuity depends upon the period for which the officer is disabled by his wound or injury for the performance of military duty.

† The rate of pension is governed by the degree of severity of the wound or injury.

Artificial appliances are supplied at the public expense to officers who have lost a limb, an eye, &c., through wounds or injuries received *in action or on flying duty.*

Pensions on Cessation of Service to Officers (as above) Disabled by Wounds, Injuries, or Disease Received or Contracted on War Service.

Officers medically certified to be disabled either wholly or partially for earning a livelihood on the cessation of their service through wounds, injuries, or disease received or contracted on war service may be granted pensions varying from 3*s.* a day to £200 a year according to circumstances. Such pension is additional to any wound pension or gratuity for which an officer may be eligible. (Officers of the Regular Army may be eligible for higher rates under the provisions of the Pay Warrant.)

Applications for wound pensions, &c., should be addressed to the Secretary, War Office, Whitehall, S.W.

Pensions to the Families of Officers (under the Rank of Colonel) of the Regular Army, the Special Reserve of Officers, and the Territorial Force, and to the Families of Officers holding only Temporary Commissions for the Purposes of the Present War.

Widows and children.	*Class A.* Families of officers killed in action or dying of wounds received in action within seven years after having been wounded.				*Class B.* Families of officers dying from disease caused by fatigue, privation, or exposure incident to active operations in the field or from wounds or injuries sustained on duty (not in action) within seven years after removal from duty for the disease or injury.	
Rank of officer (i.e., permanent rank, unless the officer holds *only* temporary rank).	Pension to widow (during widowhood).	Compassionate allowance for each child (sons till 18, unmarried daughters till 21).	Gratuity in addition to pension, &c.		Pension to widow (during widowhood). (No gratuity is payable in *these cases.*)	Compassionate allowance for each child (sons till 18, unmarried daughters till 21).
	Yearly.	Yearly.	Widow.	Each child.	Yearly.	Yearly.
	£	£	£	£ *s.* *d.*	£	£ *s.* *d.*
Lieut.-Col.	180	24	450	150 0 0	153	20 0 0
Major ...	140	21	300	100 0 0	105	17 10 0
Captain ...	100	18	250	83 6 8	75	15 0 0
Lieut. ...	80	15	140	46 13 4	60	12 10 0
2nd Lieut.	80	15	100	33 6 8	60	12 10 0

Twice the above rates of compassionate allowance may be granted to motherless children. If an officer (Class A) leaves a *daughter only* (unmarried and under 21) she may be granted, in lieu of the above rates, a special allowance varying from £40 to £90 a year according to rank. These awards are in addition to the gratuity.

If an officer (Class A) leaves neither a widow nor legitimate child, his mother, if a widow without other pension or adequate provision, may be granted a special pension varying from £40 to £90 a year according to rank, provided that she had been mainly dependent on the officer.

If an officer (Class A) leaves neither widow, legitimate child, parent, nor brother a similar pension may be granted to his sister, or sisters jointly, if unmarried, subject to the above proviso.

All applications for the grant of pensions, as above, should be addressed to the Secretary, War Office, Whitehall, S.W.

THE SCOTTISH MEDICAL SERVICE EMERGENCY COMMITTEE.

This strongly constituted committee comprises: The President of the Royal College of Physicians of Edinburgh; the President of the Royal College of Surgeons of Edinburgh; the President of the Royal Faculty of Physicians and Surgeons of Glasgow; the Dean of the Faculty of Medicine, University of Edinburgh; the Dean of the Faculty of Medicine, University of Glasgow; the Dean of the Faculty of Medicine, University of Aberdeen; the Dean of the Faculty of Medicine, University of St. Andrews; Dr. John Adams (Glasgow); Dr. G. C. Anderson (Methil); Dr. J. R. Currie (Edinburgh); Dr. John Gordon (Aberdeen); Dr. J. R. Hamilton (Hawick); Dr. John C. M'Vail (Edinburgh); Dr. John Playfair (Edinburgh); and Dr. John Stevens (Edinburgh). Dr. Norman Walker, the treasurer of the Royal College of Physicians of Edinburgh, is acting as convener, and Mr. T. H. Graham as secretary.

Dr. Norman Walker has issued through the secretaries of the divisions of the British Medical

Association three schedules or forms to be distributed to medical men, so that the Emergency Committee may be able to ascertain how far the numbers of medical men in any given area have already been reduced, and may thus be in a position to estimate what further depletion would be involved by additional offers of whole-time service. The Emergency Committee does not propose to deal with offers of part-time service at all.

The first form, Schedule A, asks for particulars concerning all medical practitioners in the given area who had been accepted for service before June 15th, 1915, and takes cognizance of those who are already engaged in part-time service.

Schedule B, dealing only with whole-time appointments, is addressed to practitioners who before June 15th had applied for a whole-time service. On this form the practitioner is asked to state whether he is over or under 40 years of age, whether his application was sent in before or after May 15th, and what was his medical work at the time of application—i.e., general practitioner, surgeon or other specialist, medical officer of health, school medical officer, or hospital resident.

Schedule C is addressed to practitioners who on June 15th had not applied for service, whole-time service alone being considered, but who are ready to do so if suitable arrangements can be made. The same information as to age and previous medical experience is required by the form.

We hope that the efforts of the Scottish Medical Service Emergency Committee to coördinate and organise medical service for military purposes will prove successful, for they have certainly been, and continue to be, of a very practical sort; and we are sure that the committee will be able to rely on the help of the British Medical Association, whose divisions make convenient centres for local activity. The convener lays great stress upon the rapid return to him at the Royal College of Physicians of Edinburgh of the filled-up schedules, substantially accurate information being required at once.

THE HEALTH OF PRISONERS IN RUHLEBEN.

The following letter, dated June 14th, has been received this week from a member of our staff who is interned at Ruhleben:—

> A fellow prisoner received to-day in a letter a cutting from an English newspaper, undated, reporting an interview with some of the men released from here, on having reached the age limit, on June 6th. The interview is said to have taken place during a stay in Rotterdam on the home journey. After various remarks about the prisoners' camps and the food the released man is credited with the statement that "50 cases of small-pox have occurred in the camps." As the fact of the internment is of itself a sufficient cause of anxiety to relatives at home, I think it is wrong to spread an unfounded statement of this kind. Let those who are lucky enough to be released stick to the truth; it is absolutely superfluous to embellish it by drawing on the imagination. I can assure you that not a single case of small-pox has occurred in the camps; the suggestion has not even circulated as a camp rumour. During the past weeks some cases of German measles have occurred; the sufferers were at once isolated and underwent treatment in the lazaretto; at the same time we were supplied with a solution of lysoform with which to disinfect our compartments, clothing, and bedding. During the past fortnight all the compartments in the stables which form our prison have been whitewashed, while a large number of men are being cleared out of the lofts and transferred to new wooden barracks. On the whole, in my opinion, the general health of the camp is very good, and we keep up our spirits by forms of athletic sport and varied entertainments. I am glad to say that I am in the best of health, and am busy the greater part of the day on behalf of my fellow prisoners.

We saw the communication to which our correspondent alludes, and can well believe that it added to the anxiety of those who had relatives interned as prisoners at Ruhleben. It happens to be very unlikely that an outbreak should have occurred and remain unknown to our correspondent.

ROYAL ARMY MEDICAL CORPS AND COMBATANT MEDICAL MEN.

Medical men at present serving as combatant officers or in the ranks may now be permitted to be transferred to the Royal Army Medical Corps on application made through their commanding officers.

Mr. Charters Symonds, consulting surgeon to Guy's Hospital, has been appointed a consulting surgeon to H.M.'s Forces in Malta, with the temporary rank of Colonel, A.M.S.

THE RED CROSS SOCIETY AND THE ORDER OF ST. JOHN.—A meeting was held at the Mansion House on June 16th in support of the Lord Mayor's special appeal on behalf of the funds of the Red Cross Society and the Order of St. John, the Lord Mayor being in the chair. The Lord Mayor spoke warmly of the work done during the past ten months, and highly commended the devoted services of the surgeons, nurses, orderlies, and voluntary aid detachments. The immediate problem was how to collect the large amounts still necessary for the carrying on of the work. During the last few weeks Sir Edward Clarke, Sir Benjamin Franklin, and Sir Frederick Treves had been canvassing City houses for subscriptions with excellent results. The Marquis of Lansdowne, who has succeeded the late Lord Rothschild (a name, as he pointed out, not likely to be forgotten in the City of London) as chairman of the council of the Red Cross Society, in proposing a resolution expressing sympathy with, and pledging support for, the Lord Mayor's appeal, approved the wisdom of the course adopted by the Red Cross Society and the Order of St. John in setting up a joint committee, which now meets regularly and conducts with perfect harmony the joint work of the two societies, thus effecting a great economy in both finances and effort. They found themselves called on to make a far greater effort than any that could have been expected, one which must be commensurate with the dimensions of a war waged with intensity, by unexampled numbers, and by methods abhorrent to all ideas of civilisation and humanity. Describing the society's work, Lord Lansdowne pointed out that they had to take care, not only of soldiers, but of sailors, and to come to the help of other countries stricken not only with injuries but with disease. Stores had been sent to East Africa, the Cameroons, Rhodesia, and China—in fact, all over the world. They had established great base hospitals at home and abroad, including the hospital for Indian soldiers in the New Forest; also some 900 auxiliary home hospitals and convalescent homes in private residences. He paid a strong tribute to the surgeons and nurses, many of whom were helping at great personal sacrifice, and emphasised the good relations maintained throughout with the Royal Army Medical Corps, largely due to the recognition of the fact that the society's operations must be kept subsidiary to those of the army, to which they were proud to serve as auxiliaries. They were endeavouring also to mitigate the lot of those unhappy ones who had been deprived of sight, and to aid in tracing the missing and wounded. He acknowledged the substantial financial aid which, in addition to the splendid services of their sons, had been rendered by the great dominions, Canada in Flanders, and Australia and New Zealand in Gallipoli. Australia alone had sent £100,000, besides shipments in kind. He specially mentioned the munificent gift of Mr. W. W. Astor of £20,000—the second of that amount. Mr. Arthur Stanley, M.P., in seconding the motion, cited two instances to show how admirably the work was done. One evening an order was received at 6 P.M. for 20,000 articles, all of which were purchased, packed, and despatched and on their way by 10 A.M. next morning. One Sunday morning the War Office informed them that a hospital was urgently required in Calais, which for valid reasons the R.A.M.C. were not in a position to supply. At 5.30 that evening a special train left Victoria carrying with it the full personnel, 120 beds, a large amount of stores, and motors and ambulances. Sir Robert Hudson showed how unnecessary expense in working was avoided, and Sir Arthur Lawley how comforts were provided near the firing line which the Royal Army Medical Corps could not be expected to provide, and how thousands of lives had been saved by the facilities for rapid transport afforded by their motors. Mr. Herbert Gibbs, Sir Dyce Duckworth, and Sir Edward Clarke also spoke. The resolution was carried. Donations varying from £20,000 to £50, and amounting to £87,455, were announced.

ROYAL NAVAL HOSPITAL, HASLAR.—A new wing is being built to the Royal Naval Hospital at Haslar out of the sum of £50,000 raised at the beginning of the war by the women of Canada and placed at the disposal of the Imperial Government. The operations in the Dardanelles have taxed the hospital's capacity to the utmost, so that the 250 additional beds which the new wing will accommodate will be of the greatest immediate utility. The new building of three floors will be isolated from the main one and will be entirely self-contained. It is expected to be completed by the end of the year.

WOUNDED ALLIES RELIEF COMMITTEE.—The committee, in conjunction with the British Registrar-General, has compiled an official register of Belgian soldiers who have been in hospital in England and of those interned in Holland and imprisoned in Germany. By this means many thousands of soldiers have been brought in touch with their families, and the register has solved some difficult cases of identity. The committee is eager to assist private persons, hospitals, or other institutions in need of information about Belgian soldiers or their families. All applications should be addressed to the committee's offices at Sardinia House, Kingsway, W.C.

The committee's typhus hospital units, which left England on June 3rd for Montenegro, are to be stationed at Podgoritza and Nikshich. Each unit consists of 100 beds, with full equipment for both surgical and fever work.

VACANCIES FOR MEDICAL OFFICERS.—We are asked to state that there are vacancies for five medical officers prepared to serve abroad in the 2nd and 3rd Line Welsh Border Mounted Brigade Field Ambulance. Pay and allowances as in the Regular Army, together with outfit and camp kit grants. Full particulars can be obtained on application to the Officer Commanding, 2nd Line Welsh Border Mounted Brigade F.A., Lambton Park Camp, co. Durham.

A NEW HOSPITAL FOR WOUNDED OFFICERS.—On June 18th General Sir O'Moore Creagh opened the new Prince of Wales's Hospital for Wounded Officers at Staines. The hospital is the gift of the Maharaja Jam Sahib of Nawanagar (whom most people will more readily recognise under the well-known name of "Ranji," the Indian cricketer). It is established in his residence at Staines, "Jamnagar," and the cost of maintenance is undertaken by himself in conjunction with the Maharaja of Kashmir and the Maharaja of Patiala.

FLEET-SURGEON LOUIS GREIG.—Mr. Kenneth Campbell, F.R.C.S., writes to us to call attention to the fact that Fleet-Surgeon Louis Greig, the famous Scottish International half-back, who took part in the Antwerp expedition, being an athlete could without difficulty have escaped into Holland with the others, but being also a surgeon his sense of duty impelled him to remain with the wounded. He is now a prisoner of war at Halle, and Mr. Campbell writes in the hope that as Fleet-Surgeon Greig is so well known some person of influence may exert himself on his behalf. It will be noted in our Parliamentary columns that in answer to a question in the House of Commons on June 17th, Lord Robert Cecil stated that an agreement had been come to by the respective countries permitting the exchange of German and British military medical officers, and that it would become operative as soon as the status of the medical personnel could be definitely settled.

PRESENTATION OF A MOTOR AMBULANCE.—On June 18th a motor ambulance, fitted up with improvements suggested by Colonel H. J. Mackay, assistant director of medical services, Wessex division, was presented by the medical men of the administrative county of Devon to the Devonshire Regiment. There were over 80 subscribers, and the ambulance, after being tested by the Royal Army Medical Corps at Woodbury Camp, Devon, will be available for service "at the front."

CORNISH MEDICAL MEN AND MILITARY SERVICE.—At a meeting held recently at St. Austell, Cornwall, to consider the appeal for an increased number of medical men for the Royal Army Medical Corps, it was resolved to call upon all medical men who were of eligible age to offer their services, and a committee was appointed to organise a scheme for carrying on the practices of those who volunteer for service. Some discussion took place in reference to the granting of medical prescription books to the dependents of soldiers and sailors who are serving, and it was decided to urge the local relief committee to exercise more care in their distribution, so as to prevent abuse of gratuitous medical services.

FREE PHYSICAL TRAINING FOR THE REJECTED.—Persons of military age who, being desirous of enlisting, have presented themselves and been rejected on the ground of deficient physical development, can now obtain, if they so desire, a month's course of physical training gratis at the Central Y.M.C.A. in the Tottenham Court-road, where owing to increased facilities 1000 applicants a month can be dealt with.

A FUND is being raised by a committee, of which the honorary treasurer is Sir Laurence Gomme, to establish and maintain a fleet of motor ambulances in Italy.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Medicines and Immature Spirit.

IN the course of the consideration of the Finance Bill in committee of the House of Commons on June 16th Mr. GLYN-JONES raised the question of the authority that was to be entrusted with the function of determining in what cases the additional duty on immature spirit was to be remitted because it was used in medicinal preparations. He suggested that this function should be discharged by an advisory body "representing medicine, pharmacy, and the Commissioners of Customs and Excise." The CHANCELLOR of the EXCHEQUER took objection to appointing a statutory body, but he promised to set up "a properly qualified medical body to advise the Commissioners of Customs and Excise what preparations may properly be described as medical preparations." This body, of course, will not owe its existence to statutory authority.

Duty-free Spirits for Hospital Tinctures.

The CHANCELLOR of the EXCHEQUER has given notice of a new clause, which he will move to insert in the Finance (No. 2) Bill, giving power to authorise the use of duty-free spirits in hospitals in the preparation of tinctures. The proposed new clause is in the following terms:—"(1) Section eight of the Finance Act, 1902 (which gives power to authorise the use of spirits without payment of duty in arts and manufactures), shall apply to the preparation in a public hospital of tinctures and other articles to be used for medical purposes in the hospital as it applies to arts or manufactures in which the use of spirits is required. (2) If the treasurer or other responsible officer of a public hospital shows, to the satisfaction of the Commissioners of Customs and Excise, that any tinctures or other articles which contain spirits or in the preparation or manufacture of which spirits were used have within the preceding six months been used for medical purposes in the hospital, he shall be entitled to obtain from the Commissioners repayment of any duty paid in respect of the spirits contained in or used in the preparation or manufacture of the said tinctures or other articles. If any person, for the purpose of obtaining any repayment under the foregoing provision, knowingly makes any false statement or false representation he shall be liable, on summary conviction, to imprisonment, with or without hard labour, for a term not exceeding six months. (3) For the purpose of the foregoing provision the expression 'public hospital' means a hospital supported by any public authority or wholly or partly out of any public or charitable funds or by voluntary subscriptions."

HOUSE OF COMMONS.

THURSDAY, JUNE 17TH.

Exchange of British and German Medical Officers.

Mr. PARTINGTON asked the Under Secretary for Foreign Affairs whether an agreement had been reached regarding the exchange of British and German military medical officers.—Lord ROBERT CECIL wrote in reply: The answer is in the affirmative, and it is hoped that the agreement will shortly be made effective. Some delay has been caused owing to the necessity for the military authorities to determine exactly the members of the British and German military medical personnel who are entitled to be exchanged.

Navy Medical Appointments.

Commander BELLAIRS asked the Secretary to the Admiralty whether the Board could see their way to increasing the remuneration given to the members of the medical profession who were appointed as naval surgeon and agent in different districts, having regard to the alterations of conditions which the war had caused since the terms were framed.—Mr. MACNAMARA answered: No reason is seen for increasing the emoluments of these posts which can always be satisfactorily filled upon the present terms, which, with a few exceptions, being based on fees for services rendered, are elastic enough to ensure that additional services during the war are recognised by additional remuneration.

Antityphoid Inoculation.

Replying to Mr. CHANCELLOR in regard to the question of antityphoid inoculation in the army, Mr. TENNANT (Under Secretary for War) said that the circular of the Research Defence Society had War Office sanction and authority and no reason was seen for withdrawing such authority.

Royal Army Medical Corps (Territorial Force).

Mr. EVELYN CECIL asked the Under Secretary for War whether officers or men of the Royal Army Medical Corps, Territorial Force, who had signed A. F. E. 624 A were liable to be transferred to combatant units; and, if so, whether it was the intention of the War Office to transfer officers and men originally enlisted in the Royal Army Medical Corps to the artillery or infantry without their further express consent.—Mr. TENNANT answered: Yes, sir; but the signing of the form is not compulsory, and if it is signed the consent of the officer or man will have been obtained. That is the purpose of the form.

Respirators for Service in the Dardanelles Operations.

Mr. G. GREENWOOD asked the Under Secretary for War whether all possible steps had been taken to provide the troops in the Gallipoli Peninsula with respirators and all other appliances to enable them successfully to resist attempts to poison them by means of noxious gases.—Mr. TENNANT replied: Yes, sir.

Infantile Mortality and Legislation.

Sir GEORGE TOULMIN asked the Prime Minister when the Bill amending the Notification of Births Act, foreshadowed by the President of the Local Government Board, would be introduced.—Mr. ASQUITH replied: I regret that I can as yet give no date when this Bill will be proceeded with.

Mr. ANDERSON asked the President of the Local Government Board whether the increase in the rate in infantile mortality was partly or largely due to the shortage of doctors and nurses, the increased industrial employment of working women, and the absence of suitable agencies and centres for child welfare; whether he would arrange, in addition to the promised legislation, to utilise the services of some proportion of the 80,000 women who had enrolled themselves for national work, with a view to establishing centres for the care of infants and so mitigating an evil which the country could not afford at any time, least of all at present.—Mr. LONG answered: I am advised that the recent increase in mortality amongst young children has been mainly due to measles and its sequelæ. I am hoping to introduce a Bill very shortly to facilitate the establishment of centres for the care of mothers and infants.

Mr. KING asked the President of the Local Government Board how many children under the age of 1 year, of or over the age of 1 year and under 2 years, of or over the age of 2 years and under the age of 3 years respectively died in England and Wales during the six months immediately preceding April 1st, 1915, and what were the numbers of such children so dying during the corresponding periods 1913–14, 1912–13, and 1911–12.—Mr. LONG wrote in reply: The number of deaths of children under the age of 1 year in England and Wales during the six months immediately preceding April 1st, 1915, was 50,209. During the corresponding periods of 1913–14, 1912–13, and 1911–12 the numbers were 49,029, 47,357, and 48,944 respectively. The number of deaths of children between 1 and 2 and between 2 and 3 years old cannot yet be given for the six months immediately preceding April 1st, 1915.

Mr. KING asked the Secretary for Scotland how many children under the age of 1 year, of or over the age of 1 year and under the age of 2 years, of or over the age of 2 years and under the age of 3 years, respectively, died in Scotland during the six months immediately preceding April 1st, 1915; and what were the numbers of such children so dying during the corresponding periods 1913–14, 1912–13, and 1911–12.—Mr. MCKINNON WOOD (in a written answer) replied: The numbers of deaths of children aged 1 and 2 years are not available in portions of years. The following are the numbers of deaths of children of less than one year old in periods named:—

Oct. 1st, 1911, to March 31st, 1912	7234
,, 1912, ,, 1913	7509
,, 1913, ,, 1914	7228
,, 1914, ,, 1915	8276

Mr. KING asked the Chief Secretary to the Lord Lieutenant of Ireland how many children under the age of 1 year, of or over the age of 1 year and under the age of 2 years, of or over the age of 2 years and under the age of 3 years, respectively, died in Ireland during the six months immediately preceding April 1st, 1915, and what were the numbers of such children so dying during the corresponding periods 1913–14, 1912–13, and 1911–12.—Mr. BIRRELL wrote in reply: The following table sets out for Ireland the numbers of deaths of infants under 1 year of age, at 1 and under 2, and at 2 and under 3 registered (1) during the six months ended March 31st, 1912, 1913, and 1914, and (2) during the quarter ended Dec. 31st, 1914. The unrevised figures of deaths of infants under 1 year of age registered during the quarter ended March 31st, 1915, are also shown, but the corresponding figures for infants between 1 and 3 years are not available.

Period.	Number of deaths registered at ages of—		
	Under 1 year.	1 and under 2 years.	2 and under 3 years.
Six months ended March 31st, 1912	4,996	1,276	606
,, ,, ,, 1913	4,835	1,301	651
,, ,, ,, 1914	4,612	1,214	600
Three months ended Dec. 31st, 1914	2,046	487	289
,, ,, ,, March 31st, 1915	2,829	—	—

Belgians in Lunatic Asylums.

Mr. LEIF JONES asked the President of the Local Government Board whether there was any public fund available to pay for the maintenance of Belgian refugees who had had to be sent to county lunatic asylums in this country so that the local rates might not be burdened with this national charge.—Mr. LONG answered: The Local Government Board has the authority of the Treasury to pay for the treatment of refugees in lunatic asylums, and in a certain number of cases have already agreed to make payments of this character.

Mr. LEIF JONES: Will payments which have already been made by the local authority be refunded by the Local Government Board?—Mr. LONG: Certainly.

Treatment of Mental Strain in Soldiers.

In the course of the debate in Committee of Supply on the Home Office vote, Mr. RENDALL called attention to the institutions in which soldiers suffering from mental strain were being treated. He said that it was a calamity that men returning from the front with their mental balance temporarily deranged should be placed under the control of the War Office. The War Office was getting hold of various asylums which he should have thought were under the control of the Home Office. The men were put into these so-called hospitals, which were really asylums, and under the control of medical men who had been attached to these asylums. The soldiers in these cases ought to be under the treatment and control of first-rate general practitioners and not under the control of the Lunacy Acts. Some new proposal ought to be formulated by the Home Office for dealing with these soldiers.

Mr. BRACE (Under Secretary for the Home Department) said: A question which has been raised in this debate is that of the men who have lost their reason in consequence of the hardships of this war, and the Government were criticised because the War Office has been selected as the authority for looking after these afflicted people. It is thought both by the Home Office and by the War Office that that is the better arrangement. If the soldiers who lost their reason in consequence of the hardships of the war were put in the ordinary asylums of the country it would, in the judgment of those who have a right to speak on this matter, be one of those experiences for which the soldiers after their recovery would not thank the nation. The army authorities have much greater latitude in regard to this matter, for they can send the men to hospitals, and when cured they will come out without any of the stigma which might attach to them if they had been confined in any of the asylums of the land. On the whole, the weight of argument is distinctly in favour of allowing the War Department to deal with these unhappy cases, and we ask honourable Members to agree with us that that is the best way of dealing with them.

MONDAY, JUNE 21ST.

Medical Students and War Service.

Sir PHILIP MAGNUS asked the Under Secretary for War whether, having regard to the fact that many of the younger university medical students of military age had been reproached for not having joined the forces of the Crown, he would state whether it was considered preferable that such students in their first or second year should accept some military position or should continue their medical studies with a view to qualification.—Mr. TENNANT replied: I am not aware of the reproaches to which the honourable Member refers. It is clear that if students in their first or second year join the combatant ranks in very large numbers there will probably be for some years after the war a serious scarcity of doctors. Any expression, therefore, of official opinion which might seem to place on them the obligation of taking up immediate military duty would hardly be in the interests either of the army or of the community as a whole.

The Health of the Expeditionary Forces.

Mr. KING asked the Under Secretary for War whether he would give some information or figures to show the prevalence of sickness in the armies at home and on active service during the war, and particularly state whether the health of the forces compared favourably with health conditions in previous wars.—Mr. TENNANT answered: I will give information, not figures. As far as important preventable diseases are concerned, the health of the Expeditionary Forces compares not only favourably with the health conditions of any previous campaign, but nothing approaching it has ever been known in the past.

TUESDAY, JUNE 22ND.

Milk and Dairies Act Postponement Bill.

Mr. HAYES FISHER moved the second reading of the Milk and Dairies Postponement Act. He said that last year two useful measures, the Milk and Dairies Act and the Milk and Dairies (Scotland) Act had been passed for the purpose of improving the milk-supplies of the country. The present Bill proposed to postpone the date on which these measures should come into operation until one year after the termination of the war, but it was provided that they might be brought into operation earlier by Orders of the Local Government Board, if that course proved feasible. The Acts in question were designed to prevent the sale of tuberculous milk, or milk exposed to contamination or dirt, or adulterated milk. More stringent regulations were imposed on the milk industry, and also more detailed and systematic inspection was required. That made for more expense. Furthermore, it was extremely difficult at present to add to the number of veterinary surgeons. It would be necessary under the Bill also to enlarge the staffs of the local authorities, but these staffs were very much depleted. More supervision on the part of the medical officers of health would also be required, but they were otherwise engaged at present. If the two Acts were not postponed it would seriously embarrass the local authorities.

Mr. RENDALL regarded the postponement of the two measures as deplorable.

Mr. DENNISS also regretted the necessity for postponement, as the question of milk-supply had a most important bearing on the question of infant mortality. He thought that medical men could have been obtained to deal with tuberculous milk and questions of sanitation.

Sir GEORGE TOULMIN recognised that there was no alternative to the postponement of the operation of the Acts owing to the administrative difficulties involved in putting them into force. He hoped that the Local Government Board would make up for the postponement later on, by the strict enforcement of the provisions when they did come into operation.

The Bill was read a second time.

Appointments.

Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

ADAMS, ALFRED, M.B., B Ch. Oxon., M.R.C.S., has been appointed Acting Deputy Medical Officer for the Second District by the Liskeard (Cornwall) Board of Guardians.

BAIRD, W. J., M.B., Ch.B. Edin., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Earls Barton District of the county of Northampton.

BALLANTYNE, ARTHUR J., M.D. Glasg., has been appointed Honorary Consulting Ophthalmic Surgeon to the Glasgow Royal Maternity and Women's Hospital.

Births, Marriages, and Deaths.

BIRTHS.

Bullock.—On June 14th, at Bigwood-road, Hampstead Garden Suburb, Elsa Gye, wife of W. E. Bullock, M.D., R.A.M.C., of a son.

Seymour.—On June 20th, at College Gates, Worcester, the wife of Harold F. Seymour, M.D., of a daughter.

Symes-Thompson.—On June 16th, at Gloucester-place, W., the wife of H. E. Symes-Thompson, M.D., of a son.

Watson.—On June 20th, at Lancaster-place, N.W., the wife of Major D. P. Watson, R.A.M.C., of a daughter.

MARRIAGES.

Allan—Woods.—On June 19th, at Christ Church, Southgate, London, N., John Allan, M.D. Edin., D.P.H., to Gertrude Buckston Agnes, youngest daughter of Josiah Woods, of London.

Ash—Pryce Jones.—On June 16th, at St. Mary Magdalene, Bersted, Bognor, Walter Martin Ash, M.B., B.S. Lond., Surgeon, R.N., to Gladys, youngest daughter of Mr. and Mrs. S. R. Pryce Jones, of "Newcourt," Bognor.

Bowden—Neville.—On June 17th, at St. John's Church, Bethnal Green, Lieutenant Ellis Campbell Bowden, R.A.M.C., to Dorothy, second daughter of Mr. and Mrs. J. Neville, of Shoreham, and late of "Leaside," Beckenham.

Bulstrode—Woolmer White.—On June 14th, at Salle Church, Christopher Victor Bulstrode, M.A., M.D. Cantab., Temporary Captain, R.A.M.C., to Marguerite, elder daughter of Mr. and Mrs. Woolmer White, of Salle, Norfolk, and Southleigh, Hants.

Chapman—Wallroth.—On June 17th, very quietly, at Sunbury-on-Thames, Donald Poyntz Chapman, Staff-Surgeon, R.N., to Florence Emily, third daughter of Mr. and Mrs. Frederick A. Wallroth, of Sunbury Lodge.

Evans—Rutherford.—On June 10th, at Dunkeld Cathedral, by the Rev. A. Howell, M.A., assisted by the Rev. W. Brownlie, B.D., A. Edward Evans, M.B., son of the late Edward Evans, C.E., and of Mrs. Evans, 3, Rotherwick Court, Golders Green, to Jessie Dorothy, second daughter of the Rev. T. R. Rutherford, M.A., Minister of Dunkeld.

Fox—Allen.—On June 16th, at Spanish-place Church, Manchester-square, London, W., Reginald A. Fox, L.D.S. Eng., D.D.S. Penn., Lieutenant, 2/4th South Lancs. Regiment, to Winnie, only child of the late Squire Winfield Allen, D.D.S., of Queen-street, Edinburgh, and Mrs. Squire Allen, of Edinburgh.

DEATHS.

Mactier.—On June 19th, at Kinnessburn, St. Andrews, William Fullarton Mactier, M.D., late Bengal Army, in his 93rd year.

Mouillot.—On June 20th, at Eton House, Harrogate, Francois Albert de Thierry Mouillot, the dearly beloved husband of Mary Mouillot, in his 56th year. Funeral Wednesday, June 23rd.

Wright.—On June 20th, at Alexandria, Lieutenant Eric Alfred Wright, R.A.M.C., of septic poisoning contracted in attending the wounded, aged 36 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

BEETLES AND RED ANTS AS CHOLERA CARRIERS.

THE danger of the transmission of disease by the domestic fly has been frequently demonstrated and is now generally acknowledged. But there are other domestic pests whose habits have not been so carefully studied. The black-beetle, for instance, conveys the cholera bacillus, at least in tropical climates. A recent issue of the *Philippine Journal of Science* contains an account of experiments made with the *Periplaneta americana* (Linn.), which infests private dwellings at Manila. This insect feeds on all kinds of organic matter, including fæces, and if precautions are not taken will crawl over food intended for human consumption. Some of these beetles were captured and fed on human dejecta containing cholera bacilli. Six hours later the fæces of the beetles were examined and found to contain cholera bacilli. In course of time the number diminished, though in one case bacilli were found 79 hours after the test meal. It would seem that the cholera bacilli do not multiply within the insect; but it is evident that if the fæces of the beetle are deposited on a damp surface the bacilli may live for a long time. One experiment showed that their vitality persisted for an entire day on a lettuce leaf and for 46 hours on an oyster. When experiments were made with guinea-pigs it was evident that the cholera germ had lost none of its virulence after sojourning for a while within the beetle. The red ant, also (*Monomorium latinode*, Mayr), is an omnivorous insect with a distinct liking for human dejecta, but the volume of its fæces is so small that experiments are difficult. Nevertheless, cholera bacilli have been detected in the bodies of red ants eight hours after they had been fed on cholera dejecta.

THE LEEWARD ISLANDS.

A REPORT on the Blue-book of this colony for the year 1913–14 has been received at the Colonial Office from the Governor, Sir H. Hesketh Bell, K.C.M.G. It states that the population at the last Census was 127,193, distributed amongst the islands as follows: Antigua, 31,394; Barbuda, 871; St. Kitts, 26,283; Nevis, 12,945; Anguilla, 4075; Dominica, 33,863; Montserrat, 12,196; Redonda, 4; Virgin Islands, 5562. During the year 3827 patients were admitted into the hospitals of the colony, and there were amongst them 354 deaths. In the central lunatic asylum in Antigua there were at the beginning of the year 129 inmates (70 males and 59 females); 53 were admitted during the year, 27 were discharged as cured, and 27 died. There are two leper asylums—one at Rat Island in Antigua and the other at Fort Charles in St. Kitts. As to the latter no statistics are given, but in Antigua there were 33 lepers at the beginning of the year, 8 were admitted during the year, and 1 died. There is no record in Antigua of any attendant at the asylum having contracted leprosy. The Alexandra Cottage Home for Incurables, Dominica, which is supported partly by voluntary contributions, maintained on an average 10 paupers. The dilapidated and insanitary collection of huts known as "Hyndman's Village" has been removed, and the site has been transformed into an open, clean, and well-drained space free from the possibility of mosquito infection. A model village is being laid out at Clare Hall. The erection and occupancy of seven cottages, provided with ample yard accommodation and each having a neat enclosed garden in front, serve as valuable object-lessons to such villages as appear to be contented with their squalid and overcrowded huts. Until 1913 the residents in St. John's, Antigua, were annually subject to the inconvenience of having their water services restricted, if not actually locked off, for periods of from four to six weeks during the dry months of the year. The erection of a large dam across the Body Pond stream has now obviated this inconvenience, and secures for the city an ample water-supply throughout the year. Much improvement has been effected in the Cunningham Hospital, St. Kitts, and one result is that the general public are now taking much more interest in the institution than was formerly the case. Both in St. Kitts and in Nevis the treatment of yaws by means of salvarsan in special wards continues to be vigorously prosecuted with excellent results. The visit of Dr. R. T. St. John Brooks, the bacteriologist sent out to report on the sanitary state of the ports of the colony with special reference to the dangers of plague, has done much to stimulate interest in sanitary questions and will result, doubtless, in improving existing conditions. Some time, however, must necessarily elapse before effect can be given to all Dr. Brooks's recommendations.

THE ROYAL EARLSWOOD INSTITUTION.

ONE of the distressing accompaniments of the war is the inevitable falling off in financial support that it must entail to many valuable philanthropic and charitable institutions. This is particularly to be regretted in the case of such of them as aim at caring for those who under no circumstances are capable of caring for themselves. A very serious sufferer is the Royal Earlswood Institution for Mental Defectives, which, in consequence of the war, has decided to forgo its annual festival dinner this year—a course which must deprive it of some £2000 of the funds needed for the support of its 500 defective inmates. Such a drop in the income would be serious at any time, but is doubly so when there is such a rise in the cost of the necessaries of life. It is sincerely to be hoped that the appeal which has been put forth by the board for an extra effort to meet this deficiency will not fall on deaf ears, and that subscriptions and donations, made payable to the secretary, Mr. Harry Howard, will be forthcoming to help to maintain the institution in its much needed activity.

P.L.M. TOURIST MOTOR-CARS.

THE Paris, Lyons, and Mediterranean Railway motor-cars, which made their first appearance three or four years ago, are announced to run daily (when not otherwise stated) this summer, between July 1st and Sept. 15th, as follows:—*Route des Alpes:* Briançon and Grenoble, viâ the Lautaret Pass; Grenoble and Aix-les-Bains, through the three passes of La Chartreuse and the Chalet (P.L.M. Restaurant, altitude 6950 feet); Aix-les-Bains and Annecy; Annecy—Le Fayet—St. Gervais-les-Bains and Evian. *Dauphiné:* Grenoble and St. Pierre-de-Chartreuse (out viâ La Placette, home viâ Le Sappey); Grenoble and Villars-de-Lans, viâ the Grands Goulets; Montdauphin—Guillestre and Abriès (horse cars). *Savoie:* Moutiers—Salins and Pralognan; Bourg-St. Maurice and Petit St. Bernard; Bourg-St. Maurice and Val d'Isère. *Jura:* Genève and St. Claude, viâ La Faucille. *Auvergne* (June 1st to Oct. 31st): St. Flour and Chaudesaigues; (June 15th to Sept. 15th): Issoire and Saint-Nectaire (twice daily). A detailed time-table may be obtained on application to the offices of the company, 179, Piccadilly, London, W.

Wanderer.—The selection of Osler's Practice and Pembrey's Pathology should meet the requirements admirably. We would suggest the addition of Essex Wynter's Minor Medicine (1914, second edition, D. Appleton and Co., London), or Leonard Williams's Minor Maladies and their Treatment (Baillière, Tindall, and Cox). For surgery we suggest Lejars' Urgent Surgery, translated by Dickie (1909, Simpkin, Marshall, and Co., price 57*s.* 6*d.* net the two volumes). An exceedingly useful book is the Newer Physiology in Surgical and General Practice, by A. Rendle Short (1914, third edition, John Wright and Sons, Limited, Bristol, price 5*s.* net). For hygiene and sanitation, an admirable little book by Lieutenant-Colonel A. M. Davies, R.A.M.C., is entitled "A Handbook of Hygiene" (1913, fourth edition, Charles Griffin and Co., Limited, London, price 10*s.* 6*d.* net.); also Hygiene and Public Health by Parkes and Kenwood (fourth edition, H. K. Lewis, London, price 12*s.* 6*d.* net).

E. F. has omitted to enclose his name and address.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

METEOROLOGICAL READINGS.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MEETINGS OF SECTIONS.

Monday, June 28th.

ODONTOLOGY (Hon. Secretaries—F. Coleman, F. R. Smyth): at 8 P.M.

Paper :
Mr. Ernest Sturridge: The Discovery of Entamœba Buccalis in Pyorrhœa Pus and Treatment by Emetin Hydrochloride.

Discussion :
The Effects of Cleft Palate Operations on the Dental Arch (opened by Mr. H. Blakeway). Speakers:—Sir W. Arbuthnot Lane, Mr. Warwick James, and others.

Casual Communication :
Mr. George Thomson: A Method of Crowning Incisor Teeth.

SURGERY.—The Members of this Section are specially invited to attend the meeting of the Section of Odontology. (See above.)

Thursday, July 1st.

OBSTETRICS AND GYNÆCOLOGY (Hon. Secretaries—C. Hubert Roberts, Cuthbert Lockyer): at 8 P.M.

Specimens :
Mr. J. D. Malcolm: (1) Papilliferous Carcinoma of the Ovary associated with Adenomyoma of the Uterus; (2) Fibromyoma Free from Attachments in a Pelvic Abscess.

Short Communication :
Dr. E. A. Barton: The Condition of the Larynx and Trachea in the Stillborn Infant and its Bearing on Artificial Respiration.

Papers :
Mr. T. G. Stevens: Adenomyoma of the Recto-vaginal Septum.
Dr. W. S. A. Griffith: Determining Causes of the Fœtal Lie *in utero*.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East.

TUESDAY.—5 P.M., Croonian Lectures:—Surgeon-General Sir David Bruce, C.B: Trypanosomes causing Disease in Man and Domestic Animals in Central Africa. (Lecture IV.)

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Dr. Simson: Diseases of Women. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. D. Armour: Operations. Dr. Pritchard: Bacterial Therapy Department. Mr. B. Harman and Mr. Gibb: Diseases of the Eye.

TUESDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations. Dr. Simson: Diseases of Women. Mr. Gibb: Diseases of the Eye.

THURSDAY.—9 A.M., Dr. Bernstein: Bacterial Therapy Department. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. D. Armour: Operations. Mr. B. Harman: Diseases of the Eye.

FRIDAY.—10 A.M., Dr. Simson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Eye Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY.—Clinics:—10.30 A.M., Surgical Out-patients (Mr. E. Gillespie). 2.30 P.M., Medical Out-patients (Dr. T. R. Whipham); Gynæcological Out-patients (Dr. Banister). 3 P.M., Medical In-patients (Dr. R. M. Leslie).

TUESDAY.—2.30 P.M., Surgical Operations (Mr. Carson). Clinics:—Medical Out-patients (Dr. A. G. Auld); Surgical Out-patients (Mr. Howell Evans); Nose, Throat, and Ear Out-patients (Mr. H. D. Gillies). Radiography (Dr. Metcalfe). 3.30 P.M., Medical In-patients (Dr. A. J. Whiting).

WEDNESDAY.—Clinics:—2.30 P.M., Throat Operations (Mr. Gillies). Children Out-patients (Dr. T. R. Whipham); Eye Out-patients (Mr. R. P. Brooks); Skin Out-patients. 5.30 P.M., Eye Operations (Mr. R. P. Brooks). 4.30 P.M., Clinical Demonstration:—Dr. T. R. C. Whipham: Selected Cases of Children's Disease.

THURSDAY.—2.30 P.M., Gynæcological Operations (Dr. A. E. Giles). Clinics:—Medical Out-patients (Dr. A. J. Whiting); Surgical Out-patients (Mr. Carson); Radiography (Dr. Metcalfe). 3 P.M., Medical In-patients (Dr. R. M. Leslie).

FRIDAY.—2.30 P.M., Surgical Operations (Mr. Howell Evans). Clinics:—Medical Out-patients (Dr. A. G. Auld); Surgical Out-patients (Mr. E. Gillespie); Eye Out-patients (Mr. R. P. Brooks).

THE THROAT HOSPITAL, Golden-square, W.

MONDAY.—5.15 P.M., Special Demonstration of Selected Cases.
THURSDAY.—5.15 P.M. Clinical Lecture.

For further particulars of the above Lectures, &c., see Advertisement Pages.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index and Title-page to Vol. I. of 1915, which is completed with the issue of to-day, will be given in the next number of THE LANCET

VOLUMES AND CASES.

VOLUMES for the first half of the year 1915 will be ready shortly. Bound in cloth, gilt lettered, price 16*s.*, carriage extra.

Cases for binding the half-year's numbers are now ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.			
One Year	£1	1	0
Six Months	0	12	6
Three Months	0	[illegible]	6

TO THE COLONIES AND ABROAD.			
One Year	£1	5	0
Six Months	0	14	0
Three Months	0	7	0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

Medical Service, a miniature Colonial, 635; at the front (Py Q), 944; organisation at the front, 1051; appreciation of, in Persian Gulf, 1197; Indian, promotions, 1256; and Scottish Emergency Committee, 36, 158, 1374
Medical Service, Army, looking backward, 305; Indian, History of, 1600–1913 (Lieut.-Col. D. G. Crawford) (review), 331; with the army, 632; Indian, pay of (Py Q), 942
Medical Sickness, Annuity, and Life Assurance Society, 200, 831, 1184
Medical Society of London, abandonment of second half of session (Dr. G. E. Gask and Dr. Herbert French), 152; (see also Medical societies)
Medical students and war service (Py Q), 1269

MEDICAL SOCIETIES.

Æsculapian Society.—Exhibition of skiagrams demonstrating a case of appendix dyspepsia; Exhibition of cases, 18, 184, 442—Colitis and its treatment, 376—Jaundice, 605—Exhibition of cases and skiagrams, 708, 860
Bradford Medico-Chirurgical Society.—X ray demonstrations; Functions of the connective tissue, 280 — Urinary incontinence; Vertigo; Indiscriminate use of purgatives, 755—Some remarks on diagnosis in abdominal cases; Some remarks on toxic amblyopia; End-results of gastro-enterostomy, 1028
Edinburgh Obstetrical Society.—Presidential address, 184
Harveian Society of London.—Exhibition of cases, 280, 1081—Rodent ulcer, 497—Discussion on cerebro-spinal meningitis, 1026
Hunterian Society.—Demonstrations, 211—Apparatus for producing pneumothorax; Vaccine-therapy, its present scope, 555—Exhibition of cases and specimens, 659
Liverpool Medical Institution.—Pityriasis rubra; Treatment of displacement of uterus; Incoördination of function in relation to disease; Annual meeting, 235—Principles and practice of the prophylactic use of typhoid and other vaccines, 555
London Dermatological Society.—Exhibition of cases, 260, 525, 683, 970—The inhibitive action of X rays upon malignant growths, 970
Medical Society of London.—Radiography in its relation to the present war; X ray director for the removal of foreign bodies in the tissues; Telephone attachment in surgery, 235—Discussion on gunshot wounds of the head, 373—Continued discussion on radiography in its relation to war, 439—Outbreak of toxic jaundice of a new type among aeroplane workers, 555—Election of officers, 1028—Exhibition of early books on naval and military surgery and other objects of medical and surgical interest, 1080
Medico-Psychological Association of Great Britain and Ireland.—Meningo-vascular syphilis, 441—"Anger"; Research in connexion with causation of insanity, 1136; Annual meeting in London, July 22nd, 1180
North of England Obstetrical and Gynæcological Society.—Marsupialisation of degenerated and infected fibroids; Rupture of uterus with fatal result; Exhibition of specimens, 330
North Staffordshire Medical Society.—Exhibition of cases and specimens, 889, 970, 1180
Ophthalmological Society.—Annual congress, 717, 928, 978
  Papers: Diagnosis and treatment of bony tumours of the orbit (Mr. C. Wray); Intranasal treatment of dacryocystitis (Mr. W. D. Harmer); Injuries to the eye in warfare (Capt. A. W. Ormond); Cure of spontaneous detachment of retina by multiple scleral puncture (Mr. C. H. Walker); Retinitis pigmentosa treated by trephining (Mr. M. S. Mayou), 928—Papilloma removed from the upper canaliculus (Mr. F. A. Juler); Lymphangioma of the orbit with hæmorrhages (Dr. G. Mackay, Edinburgh); Discussion on ophthalmic injuries in warfare (Mr. W. H. H. Jessop, &c.), 929—Discussion on detachment of the retina (Mr. M. S. Mayou, &c.), 978—Angiosarcoma of retina (Mr. C. Walker); Eye symptoms in Kaposi's disease (xeroderma pigmentosum) (Mr. F. R. Cross), 979—The microscopical anatomy of diseases of the eye (Mr. A. Greeves); The pathological anatomy of the retina and choroid after the complete and partial cutting-off of their respective blood-supplies (Mr. A. Greeves); Apparent accommodation with aphakia (Mr. T. Collins); Epibulbar epithelioma completely disappeared after the application of radium bromide (Mr. T. Collins), 980—(1) Dystrophies of cornea and glaucoma, (2) primary pneumococcal choroiditis, (3) artificial maturation of cataract, (4) sarcoma of socket (Mr. G. Clegg); Dissolving senile cataract in the early stages (Mr. W. B. I. Pollock); The capsular opacities of Morgagnian cataract (Lieut.-Col. H. Herbert); Hyperplasia with colloid and amyloid degeneration of the episcleral and circumdural fibrous tissues (Mr. G. Coats), 981
  Demonstrations: Choroid and retina of the fruit-bat (Mr. G. Coats); Parasites in eyelid and anterior chamber in animals (Mr. Coats); Filaria from the anterior chamber of the horse (Lieut.-Col. W. G. Pridmore and Mr. Coats), 929
  Clinical meeting: Exhibition of cases, 979
Roentgen Society.—X ray localisation methods; Discussion on methods of protection of X ray operators, 1345
Royal Academy of Medicine in Ireland (Sections)—
  Anatomy and Physiology.—Exhibition of skiagrams and specimens; Estimation of the degree of brain development from endocranial casts; Electrolytic reduction; Electrocardiographic method of estimating condition of heart muscle; Heart-block produced by yohimbin and quebrachin; Action of rennin; Effect of racemic arginin on excretion of creatinine and creatine; Urinary acid index; Electrocardiograph and its usefulness in diagnosis and prognosis, 1180
  Medicine.—Exhibition of case; Radium therapy in uterine cancer, 440—Exhibition of cases of lupus vulgaris; X ray treatment of ringworm; Prophylactic inoculation against tuberculosis, 708—Dermatitis herpetiformis; Urinary concretions; Cases of Landry's paralysis, myasthenia gravis, and epileptic automatism, 1135—Case of leprosy; Use of vaccines in treatment of respiratory diseases, 1296
  Obstetrics.—Fixed chronic retroversion of the uterus; Exhibition of specimens, 328
  Pathology.—Adeno-carcinoma (mesothelioma) of the kidney; Congenital cystic kidneys, 1234
  State Medicine.—The Vaccination Acts, 376—The recent outbreak of cerebro-spinal meningitis in the Dublin military districts, 914
  Surgery.—Exhibition of specimens; intestinal stasis, 132—Exhibition of cases, 440, 1295—Theory and technique of a new method of radium therapy, 441—Exhibition of patients; The rôle of high-frequency current in the treatment of tumours of the bladder, 659—Localisation of modern projectiles, with reference to a special method of surgical technique in their removal, 1027—Bridge method of skin grafting, 1295
Rouen Medical Society (R.A.M.C.).—Discussion on typhoid fever, 602
Royal Society of Medicine (Sections)—
  Anæsthetics.—The influence of preliminary narcotics on general anæsthesia, 913
  Clinical.—Exhibition of clinical cases, 372, 600; So-called frost-bite, 372, 627—Osteotomy of the tibiæ; Self-mutilation of the penis in boys, 1079
  Dermatology.—Exhibition of cases and specimens, 18, 234, 496, 707, 969
  Electro-therapeutics.—Discussion on the electrical treatment of wounds, sinuses, frost-bite, and sprains, 494—Exhibition of cases and specimens, 658—The late Dr. Lewis Jones, 858—The standard meal for X ray examinations; Electrical treatment of stasis; Glycosuria in chronic intestinal stasis; Simple peptic ulcer of œsophagus treated by ionisation; Exhibition of skiagrams, 859
  Epidemiology and State Medicine.—Discussion on the epidemiology of cerebro-spinal meningitis, 553
  Laryngological.—After-treatment of submucous resection of the nasal septum without splints; Exhibition of cases and specimens, 373, 657, 1080—Annual general meeting; Cases of warfare injuries and neuroses, 1080
  Medicine.—Hypernephroma, 492—Latent Addison's disease, 493—Leukæmia, 968
  Obstetrics and Gynæcology.—Exhibition of cases and specimens, 131, 1079—Sarcoma of cervix and of broad ligament; Cancer of cervix; Hysterectomy for ante-partum hæmorrhage, 131—Ruptured unilateral solid cancer of ovary removed; Squamous-celled carcinoma; Inversion of uterus; Exhibition of specimens, 371—Unusual degeneration of the cervix; The "Dublin method" for the third stage of labour; The Alexander-Adams operation, 806—Infundibulin in primary uterine inertia and in the induction of labour; Complete inversion of the vagina; Diphtheritic stenosis of the vagina; So-called true hermaphroditism, 1079

Ophthalmology.—Cerebral degeneration associated with macular changes; Exhibition of cases and of a trench periscope, 328—The Montessori system and its use for children with defective vision; Education of children with defective vision; Exhibition of clinical cases, 601—Exhibition of cases; Retinitis of pregnancy, 1294

Otology.—Tuberculosis of the auditory apparatus, 439

Pathology.—Tyrosine as an aid in the demonstration of the *de novo* origin of living organisms; Aneurysm of the left ventricle; Arc light method of isolating typhoid organisms and agglutination method, 1024

Psychiatry.—The application of physiology to the study of mind in health and disease, 279—The thyroid gland and mental disorder, with especial reference to hypothyroidism; Exhibition of cases and specimens, 1025

Study of Disease in Children.—Exhibition of cases and specimens, 73, 233, 754; Suppurative parotitis after pneumonia, 754—Localising brain symptoms as early events in tuberculous meningitis; Demonstrations of cases and specimens, 1179

SOCIETY OF MEDICAL OFFICERS OF HEALTH.—Criminal abortion and abortifacients, 184—Civil health officers and assistance to the military authorities in time of mobilisation or war, 442—Etiology of diphtheria, 658—School medical service group, 724

ULSTER MEDICAL SOCIETY.—Diagnosis in phthisis; Acute intestinal obstruction; Scarlet fever in Belfast, 133—Exhibition of specimens, 280—Cæsarean section, 377—Instantaneous skiagraphy; Mechanism of enlarged prostate, 497—Surgical aspects of hyperacidity, 673—Election of office-bearers, 1305

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—Exhibition of specimens, 304, 330—X ray appearance of some common disorders of the stomach, 604—Exhibition of cases, 859—Some developments in the management of labour, 1027—Functional palsies and their recognition, 1234

Medical staff of the Viceroy of India, 260
Medical students, enlistment of (Py Q), 413; military, strike at Lahore, 1094; and war service (Py Q), 1377
Medical students, shortage of, 30
Medicated gelatine lamels, 283
Medicinal compounds, effect of the spirit tax on the cost of, 975; alcohol, duty on (Py Q), 1059

MEDICINE AND THE LAW.—Medical certificates and the educational authorities; Prescriptions by telephone; A pernicious quack sentenced, 340—Dr. F. J. Waldo's annual report; Stevens *v.* British Medical Association, 1043; The verdict "Guilty, but insane," 1199—London Insurance Committee and allotment of insured persons, 1200—Modern echoes of a famous crime: trial of the Stauntons, 1363

Medicine case, personal, for use on active service, 214
Medicine, Clinical, a Treatise on (Dr. W. H. Thomson) (review), 20; some uses of static electricity in, and surgery (Mr. J. J. Grace), 180; Text-book of Pathology for Students of (Dr. J. G. Adami and Dr. J. McCrae), second edition, 1914 (review), 135; and surgery in war (leading article), 242; in Germany, popular, 262, 306; Forensic, and Toxicology, fifth edition, 1914 (Dr. J. D. Mann) (review), 280; women in, the opportunity for, 563; Catechism Series (review), 1237
Medicine, preparation of, and immature spirits (Py Q), 1003, 1106, 1143, 1376; and the Civil List, 1372
Medico-legal points in connexion with the new British Pharmacopœia, 503
Medico-military papers, 158
Medico-Psychological Association of Great Britain and Ireland (see Medical Societies)
Melbourne University, Medical School of, 387; practical loyalty, 1368
Mellor, Mr. J. W., Introduction to Modern Inorganic Chemistry (review), 24
Meltzer, Dr. S. J., magnesium sulphate in the treatment of tetanus: a simple apparatus for pharyngeal insufflation, 1330
Melville, Dr. S., value of "tidal percussion" as early diagnostic sign in pulmonary tuberculosis, 658
Memory, loss of, due to exposure (Dr. H. J. Cooper), 278
Mencière, Dr. L., embalmment of septic wounds, 269
Meningitis, cerebro-spinal, epidemic (leading article), 612; (Mr. E. N. Butler), 692; (Dr. A. C. Coles), 750, 1046; collosol argentum in, 784; epidemic (Dr. F. E. Batten), 964; case of (Dr. H. J. Alford), 967
Meningitis, cerebro-spinal, 184, 464, 516, 828, 829; discussion on, 553, 673, 1026; (Py Q), 525, 526; in Belfast, 821, 876; meningococci found in peripheral blood films, 881; in the Dublin military district, 914; vaccination against (Py Q), 1106

Crile on the Origin and Nature of the Emotions

Dr. Crile's new work on the origin and nature of the emotions gives the fundamentals of his *kinetic theory of shock*, and shows the *pathologic identity of surgical and emotional shock*. All the facts here established are founded on personal experimentation, later verified by clinical observations. The cell-changes produced in the brain, suprarenals, and liver by the various emotions, and the *great importance of sleep* in restoring these organs to their normal state after emotional exhaustion are described. The relation between the physical state of brain-cells and brain-functions, a mechanistic view of psychology, a mechanistic theory of disease; pain, laughter, and crying; the influence of acidosis on anæsthesia are included. The book is an instructive companion to the author's work on "anoci-association."

Octavo of 240 pages, illustrated. By GEORGE W. CRILE, M.D., Professor of Surgery, Western Reserve University, Cleveland. Cloth, 13s. net.

Braasch's Pyelography

JUST OUT

This new work is a collection of 296 pyelograms selected from several thousand made at the Mayo Clinic, and an accompanying text interpreting the pyelograms in diagnostic terms. It includes the history of pyelography, the exact technique (selection of medium to be injected, preparation of solution, method of injection, source of error, injurious results, &c.), outlines of normal pelves, outlines in the various pathological conditions, and in abnormalities. It is a most complete work, and the reader will find it extremely valuable in diagnosing by this means conditions of the renal pelvis and ureter.

Octavo of 323 pages, 296 pyelograms. By WILLIAM F. BRAASCH, M.D., Mayo Clinic, Rochester, Minn. Cloth, 21s. net.

McConnell's Dental Pathology & Bacteriology

JUST OUT

This work is written expressly for dentists and dental students, emphasising throughout the application of pathology and bacteriology in dental study and practice. There are chapters on retrogressive processes, cell division, granulomas, progressive processes, tumours, special mouth pathology, sterilization and disinfection, bacteriological methods, specific micro-organisms, infection and immunity, and laboratory technique.

12mo. of 309 pages, illustrated. By GUTHRIE McCONNELL, M.D., Assistant Surgeon, Medical Reserve Corps, U.S.N. Cloth, 10s. 6d. net.

Abbott's Essentials of Medical Electricity

JUST ISSUED

This new work gives the essentials of medical electricity. It contains chapters on galvanic electricity, galvanic cells and batteries, electrolysis, cataphoresis, electrotonus, faradic electricity, sinusoidal electricity, technique of therapeutic application and prescriptions, electrodiagnosis, static electricity, high frequency currents. To the chapters of interest to nurses a number of review questions have been appended.

12mo. of 132 pages, illustrated. By GEORGE KNAPP ABBOTT, M.D., Professor of Clinical Medicine, College of Medical Evangelists, Loma Linda, California. Cloth, 6s. net.

SECOND EDITION. With 226 Illustrations. 10s.

THE MEDICAL PUBLISHING COMPANY, LTD., 23, BARTHOLOMEW CLOSE, E.C.

LISTERINE

is an efficient, non-toxic antiseptic of known and definite power, prepared in a form convenient for immediate use.

It is a saturated solution of boric acid, reinforced by the antiseptic properties of ozoniferous oils.

It is unirritating, even when applied to the most delicate tissue.

It does not coagulate serous albumen.

It is quite generally accepted as the standard antiseptic preparation for use where a poisonous or corrosive disinfectant can not be safely used.

It is particularly useful in the treatment of abnormal conditions of the mucosa, and admirably suited for a wash, gargle, or douche in catarrhal conditions of the nose and throat.

In proper dilution, it may be freely and continuously used without prejudicial effect, either by injection or spray, in all the natural cavities of the body.

There is no possibility of poisonous effect through the absorption of Listerine.

A pamphlet descriptive of the antiseptic, and indicating its utility in medical, surgical, and dental practice, may be had upon application to the manufacturers, Lambert Pharmacal Co., Locust and Twenty-first Streets, St. Louis, Missouri, U.S.A., or to their British Agents, Messrs. S. Maw, Son and Sons, 7-12, Aldersgate-street, London, Eng., but the best advertisement of Listerine is

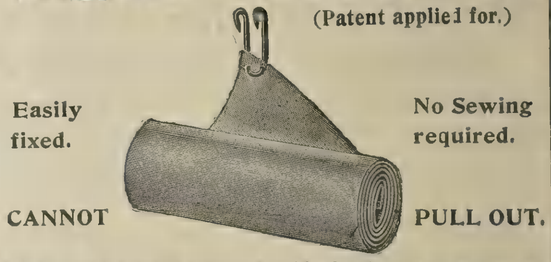
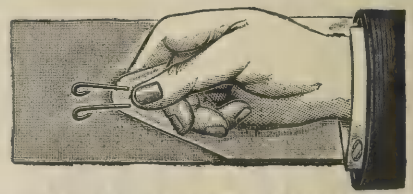
THE "KIRBY" HOOK PIN

(Patent applied for.)



Easily fixed.
No Sewing required.
CANNOT
PULL OUT.

THIS Hook Pin has been scientifically designed to form an EASY and SAFE fastening for Bandages, Puttees, &c.



Insert the Hooks in the under side of the end of Bandage, push through, turn over, and fasten into the material.

Made in various sizes, with blunt points well turned in for open-woven Bandages, and in larger sizes with sharper points for Puttees, Binders, and thicker materials.

Owing to the points being turned in towards the shanks of the Hook Pins there is no danger of scratching, even when used with thin Bandages next the skin.

BOVININE

Reports, of a most positive character, multiply from Nursing Institutions and Sanatoria confirming the pronounced efficacy of Bovinine in the treatment of Nervous complaints. In these conditions Bovinine constitutes a perfect nutritive pabulum, a rapid and favourable response invariably attending its use.

Its efficacy in the following conditions has the endorsement of all medical men who have closely observed its effect: **Anæmia, Anorexia, Asthenia, Collapse, Hæmophilia, Hæmorrhages, Pyrosis, Septicæmia, Shock, Tabes,** &c.

By its powerful nutritive-tonic properties nerve energy is rapidly promoted.

On sale at all Pharmacies at 1s., 2s. 9d., and 4s. 6d. per bottle.

"Lives *of* Great Men Oft' Remind Us"

When marble and stone have crumbled to dust, the words and deeds of great men will still remain.

J. MARION SIMS is recognised as having been one of the world's greatest surgeons and has been justly called the "Father of Gynecology."

He Said *"For severe Dysmenorrhea, I have found Hayden's Viburnum Compound of great service." Vol. 2 of Grailly Hewitt on Disease of Women, with notes by J. Marion Sims, M.D.*

The opinion of J. Marion Sims as to the therapeutic value of Hayden's Viburnum Compound is being continuously substantiated by thousands of physicians who are daily employing the genuine H.V.C. in their practice.

Not only in Dysmenorrhea, but in Menorrhagia, Rigid Os, Post Partum and After Pains, and in other gynecological and obstetrical conditions where indicated, **HAYDEN'S VIBURNUM COMPOUND** has proven dependable.

Administered in hot water in teaspoonful doses, the original H.V.C. will not disappoint you. Send for sample for clinical observation, and literature.

Indisputable authoritative evidence of the therapeutic value of the component parts of Hayden's Viburnum Compound is contained in the booklet "The Reason Why." Let us send it to you.

ANTIKAMNIA TABLETS

IN RHEUMATISM AND NEURALGIA.

In the administration of remedies to relieve **Pain,** the element of exhilaration should be considered, as many produce such delightful sensations as to make them dangerous to use.

Such is not the case with **Antikamnia Tablets.** They are simply pain relievers—not stimulants—not intoxicants. Their use is not followed by depression of the heart.

In cases of **Acute Neuralgia,** tested with a view of determining the analgesic properties of Antikamnia, it has been found to exceed any of its predecessors in rapidity and certainty of the relief given. **Neuralgia, Myalgia, Hemicrania,** and all forms of **Headache, Menstrual Pain,** &c., yield to its influence in a remarkably short time, and in no instance has any evil after-effect developed. Strongly recommended in **Rheumatism.** The adult dose is one or two tablets every one, two, or three hours. To be repeated as indicated. All genuine Tablets bear the AK monogram.

TO TREAT A COUGH. Antikamnia & Codeine Tablets are most useful. It matters not whether it be a deep-seated cough, tickling cough, hacking cough, nervous cough, or whatever its character, it can be brought under prompt control by these Tablets. To administer Antikamnia & Codeine Tablets most satisfactorily for coughs advise patients to allow one or two Tablets to dissolve slowly upon the tongue and swallow the saliva. For night coughs take one on retiring.

ANALGESIC. ANTIPYRETIC. ANODYNE.

ANTIKAMNIA TABLETS, 5 gr. ANTIKAMNIA & CODEINE TABLETS
Supplied in 1-oz. packages to the Medical Profession.

THE ANTIKAMNIA CHEMICAL COMPANY, 46, Holborn Viaduct, London.

IF in Vi-Casein we had produced nothing more than an exact substitute for Sanatogen, that alone would be sufficient reason for asking Medical Men to prescribe Vi-Casein, but

Vi-Casein, both as regards its tonic value and its taste is an improvement on Sanatogen.

Vi-Casein is one-third less in price than Sanatogen.

Sanatogen is German-owned and every sale makes profits to be handed at some future date to those who are fighting against us.

Vi-Casein is made in Britain, by a British process, employing only British workpeople and British Capital.

Testing Sample sent free.

Where Lecithin is indicated—

IF it be desired to administer the organic glycerophosphates of Lecithin-Ovo in solution, the most palatable and efficient medium is Junora wine. Junora may be prescribed with advantage for malnutrition, anæmia and debility, during convalescence and in other cases where Lecithin is indicated. It is an alcoholic beverage (about the same strength as Burgundy) because alcohol is the only practicable solvent for Lecithin. Junora creates appetite, increases the activity of the blood-forming organs, strengthens the nervous system and improves the whole nutritive condition.

Humphrey Taylor & Co.

By Appointment to H.M. The King.

JUNORA is supplied in two strengths :—		Per bottle.
A. About ¾-gr. Lecithin-Ovo products to the oz.	—	2/11
B. About 5-grs. Lecithin-Ovo products to the oz.	—	4/-

SPECIAL TERMS TO MEDICAL MEN

A full-sized trial bottle of Junora will be sent free to any Doctor on Application.

JUNORA
WINE OF HEALTH

Proprietors: Messrs. HUMPHREY TAYLOR & CO., Ltd.
(Established 1770)
45, NEW OXFORD STREET, LONDON, W.C.

By Appointment to H.M. The King.

THE Lecithin-Ovo made by Messrs. Humphrey Taylor & Co. is the finest Lecithin obtainable. It is made exclusively in England, and is of uniform purity and efficiency. Every process of its manufacture has been examined and tested by the leading authorities on Lecithin in Great Britain, and their considered opinion is that Lecithin-Ovo thus obtained is superior in quality to any foreign preparation of Lecithin.

Lecithin-Ovo

40/- per lb. **3/6** per oz.

Lecithin-Ovo Capsules { 1½ grs., **4/6** per 100.
3 grs., **8/6** per 100.

Lecithin-Ovo Powders { Finest quality from 10 to 30 per cent. strength at lowest prices.

Samples and quotations sent free on application to the Proprietors, who invite comparison of their quality and prices.

In DIABETES, GOUT, RHEUMATISM, &c.,

"G.B." Diabetes Whisky

(Late Proprietors: GEO. BACK & CO., LTD.)

PURE MALT. **SUGAR FREE.**

"THE LANCET," *October 5th, 1889.*

"G.B." DIABETES WHISKY.—This Whisky is almost absolutely free from extractive matter. It yielded to our analysis only 0·0275 per cent. of solid extract and 0·005 of ash. The alcohol amounted to 44·65 per cent. in weight, equal to 91·60 of proof spirit. It has scarcely any colour, and certainly deserves its name.—(Page 701.)

5/- per bottle, 55/- per dozen, carriage paid.

GUARANTEED TEN YEARS OLD.

Samples and analyses will be sent on application to the Proprietors.

HUMPHREY TAYLOR & CO., Ltd. (Est. 1770) Bloomsbury Distillery, London, W.C.

Prescribed by the Medical Profession for 35 years.

The BRITISH MEDICAL JOURNAL says:
"Time and use have justified the claims put forward for these preparations."

Cases of persons subsisting upon *BENGER'S FOOD*, mainly or entirely, for several years.

There will be many medical men, who can, in their own experience, confirm the value of Benger's Food, as indicated in the following excerpts from genuine unsolicited and voluntary letters.

PLUMSTEAD, KENT.

"I have been living entirely on Benger's Food for seven years, it being the *only* food I can get to suit me." Mrs. C——.

ROTTINGDEAN, near BRIGHTON.

"Having been a sufferer from gastric trouble for the past 8 years, and not being able to take any solid food, I am living on Benger's Food, and am now weighing 13 stone 2 lbs. My age is 71 years." J. M——.

GILLINGHAM, KENT.

"I have lived on Benger's Food alone for over 12 years. I have tried other foods, but cannot take them without feeling sick." M. A. G——.

BISHOPSTON.

"I have thought you would be interested to know that during the past eight years I have been living practically on Benger's Food. I cannot speak too highly of the good it has done me. It was ordered for me by my medical man." M. L——.

NEWCASTLE, STAFFS.

"I live on Benger's Food alone, and have done so for a number of years. *Five* years ago the doctor never thought I should be able to leave my bed." E. D——.

Benger's Food is prepared with fresh new milk, with which it combines to form a delicate food cream, rich in all the elements necessary to sustain life.

BENGER'S Food

for INFANTS, INVALIDS, AND THE AGED,

is sold throughout the World by Chemists, &c., in sealed tins.

A physician's sample, with full particulars, will be sent post free on application to any member of the medical profession.

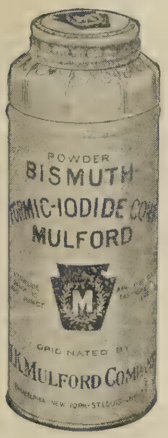
BISMUTH-FORMIC-IODIDE COMP. POWDER

The Ideal Dry Surgical Dressing



Bismuth-Formic-Iodide Comp. Powder is indicated in all acute or chronic inflammations of the skin and subcutaneous tissues, such as exist in specific or non-specific skin diseases, ulcers, wounds, and suppurating surfaces, burns, scalds, abscesses, &c. It is of particular value in the treatment of chronic indolent leg-ulcers and in local diseases of a markedly inflammatory and rapidly progressive type, such as serpiginous and phagadenic ulcerations, existing independently of or complicating venereal diseases. Bismuth-Formic-Iodide Comp. is an aseptic and unusually antiseptic astringent alterative, analgesic and stimulating dry dressing for wounds, ulcerations, discharging sores, skin diseases, &c.

Vitafer

The Premier TONIC FOOD.

VITAFER is no hastily concocted preparation to meet the war demand for goods of British origin. Some of these are practically only dried skim milk powder with glycerophosphate, and are only of about half the real nerve nutritive value of such a preparation, as VITAFER, and, what is of serious moment to Diabetic patients, contain the whole of the milk sugar from which VITAFER is carefully freed.

To illustrate this point, we submit side by side the analysis of VITAFER and of one of the newest of these numerous claimants.

	VITAFER	THE TYPICAL EXAMPLE
Nitrogen	10.30	4.98
Chemically pure proteins	68.40	31.40
Sugar	absent	42.31

Comment is surely needless!

VITAFER contains certain substances essential to nutrition, known as Vitamines. In the case of Foods in which Ether is used for extraction, they are deprived of these valuable properties.

GOLD MEDAL awarded to VITAFER at the International Congress of Medicine, London.

VITAFER is sold at prices which bring it within the reach of all classes. — 2 oz. Tins, 1/3 4 oz. 2/- 8 oz. 3/6 16 oz. 6/-

Uric Acid Crystals.

GOLD MEDAL, LONDON, 1908
Grand Prix, Nancy and Quito, 1909

COMMUNICATIONS:
Academy of Medicine, Paris, 10th Nov., 1908.
Academy of Sciences, Paris, 14th Dec., 1908.

URIC ACID is never found free in the organism. It always exists in a state of combination with Soda, Ammonia, &c.; it forms biurates or quadriurates, which are complex and not easily soluble.

URODONAL by reason of its special composition, is able to effect the double chemical decompositions which liberate the Uric Acid from the combinations where it is fixed, and cause it to be easily eliminated in the urine.

URODONAL is a most powerful solvent of **URIC ACID,** because it can destroy its organic combinations.

URODONAL, JUBOL, GLOBEOL, FILUDINE,
Prepared by J. L. CHATELAIN, 2 & 2 bis, rue de Valenciennes, Paris.
Can be obtained from all Chemists and Stores, or from the London and Colonial Agents,
HEPPELL & CO., Foreign Chemists, 164, Piccadilly, W.

A TRUSTWORTHY
UTERO-OVARIAN TONIC
AND ANODYNE

Liquor Sedans

Each fluid ounce represents:—

Viburnum Prunifolium (Black Haw)	60 grains.
Hydrastine to represent Fl. Ext. Hydrastis	30 minims.
Piscidia Piscipula (Jamaica Dogwood)	30 grains.
Aromatics	q.s.

DOSE:—½ to 1 fluid drachm in hot water several times daily.

LIQUOR SEDANS has been abundantly proved, during many years of continuous use by eminent gynæcologists in all parts of the world, to be a most efficient remedy in **amenorrhœa, dysmenorrhœa, menorrhagia, acute or chronic inflammation of the womb and ovaries, threatened miscarriage, etc.** It is often effectual in stubborn cases which have resisted other treatment.

SELECTIONS FROM CLINICAL REPORTS.

Disorders of Menstruation.

"Liquor Sedans is a useful tonic which can be given with iron or other preparations to those who are debilitated by excessive losses or suffering."

Edinburgh Medical Journal, July, 1900.

Endometritis.

"Milder cases of so-called endometritis often yielded to the administration during the week preceding the menses of the combination of hydrastis and viburnum prunifolium found in Liquor Sedans."

Glasgow Medical Journal, June, 1905.

Cancer of the Uterus.

"In the treatment of cancer which is beyond the stage for operative interference, Liquor Sedans is superior to opium. In my experience, it causes a considerable diminution and sometimes an absolute cessation of pain."

New York Lancet, June, 1901.

Liquor Sedans is supplied in bottles containing 4, 8, 16, and 80 fl. ounces.
Gelatin Globules, each containing the equivalent of 1 fl. drachm of Liquor Sedans, are supplied in boxes of 12, 25, and 100.

Please specify "P., D. & Co." on all prescriptions for the above-mentioned.

Parke, Davis & Co., London, W.

Advances in Diagnosis and Treatment

Typhoid and Paratyphoid Diagnostic

As suggested by Dr. Dudgeon and used by the

Army Bacteriological Laboratories.

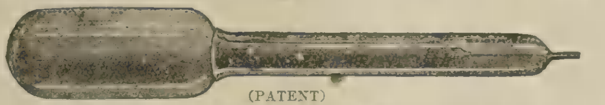
An easily prepared and thoroughly efficient medium for cultivating bacteria from the blood in cases of Typhoid and Paratyphoid Fever. The bile-salt medium is contained in gelatine capsules, one of which is dissolved in 25 c.c. of distilled water, sterilised, and mixed with 10 c.c. of blood drawn directly from a vein.

Typho-diagnostic Capsules, sufficient for 12 tests, with full description of technique - 3/- per box.

"Hyposol" Vacuum Extractor

(Trade Mark)

For collecting samples of blood, etc., under ideal conditions of sterility and directly into the culture fluid.



(PATENT)

The apparatus consists of a vacuum bulb suitably connected with a needle, so that on breaking the neck of the bulb within the india-rubber tube blood can be drawn from a vein, or other fluid collected under absolutely sterile conditions.

The following forms are supplied :

No. 1—25 c.c. total capacity ; to take up 10 c.c. of fluid - -	1/3 each
No. 2—25 c.c. : vacuum 10 c.c. ; containing 1 c.c. Citrate solution	1/3 each
No. 3—25 c.c. : vacuum 10 c.c. ; with glass beads - - -	1/6 each
No. 4—65 c.c. total capacity containing 50 c.c. nutrient bouillon with a 10 c.c. vacuum - - - - - - -	2/6 each
No. 5—50 c.c. total capacity containing 25 c.c. bile-salt solution with a 10 c.c. vacuum (for diagnosis of Typhoid and Paratyphoid Fever) - - - - - - -	2/- each

"Hyposol" Vacuum Extractors containing other culture fluids are prepared specially to order.

TRADE MARK
A.D. 1715

'Bynin' Amara

TRADE MARK

FORMULA:

Quinine Phosphate	$1\frac{1}{2}$ grains.
Iron Phosphate	2 ,,
Nux Vomica Alkaloids (equal to Strychnine)	$\frac{1}{16}$ grain.
"Bynin," Liquid Malt	1 ounce.

"A distinct advance on Easton's Syrup"

THE LANCET.

"Bynin" Amara

is an analogue of Easton's Syrup, over which it has, however, marked advantages. In this product, "Bynin," a pure, nutritious, and highly active Liquid Malt, supersedes the inert basis of the official preparation.

"Bynin" Amara

is vastly superior to Easton's Syrup; the dose can be regulated with exactness; the digestive organs are reinforced and the system is invigorated by its powerful tonic action. It not only assists the digestion of food, but conserves and ensures complete assimilation.

Explanatory Pamphlet and Sample Free to Medical Men.

The Dietetic Treatment of Disease.

The 'Allenburys' DIET

Invaluable in Sickness and Convalescence.

MEDICAL TESTIMONY

The following unsolicited testimonials illustrate the value of the 'Allenburys' Diet.

Obstinate Vomiting

"I used your Diet with **complete success in a case of most intractable vomiting, it being the first and only substance which the patient retained;** but after its use for a few days she was able to ascend the dietary scale in a steady rise.

. . . . House Surgeon.

Dyspepsia and Old Age

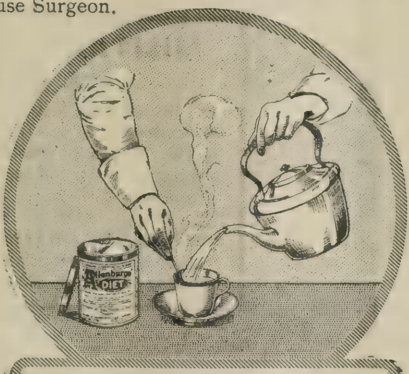
"Please send me by return (as the case I require it for is a very urgent one) six tins of Diet. I have found it **most beneficial in a case of an aged dyspeptic,** and I shall have much pleasure in recommending it wherever possible.

. . . . M.D.

An Intractable Gastric Case

"I may say that I tried, with very great success, your Diet on an intractable gastric and intestinal case. **I verily believe it was the means of saving the man's life,** for he could digest nothing until I gave him **your Diet, which speedily brought him round, and enabled him to tide over a very critical period of his ailment.** I certainly consider the nutritious qualities of your Diet to be of a high order."

. . . . . . M.B.



MADE IMMEDIATELY BY ADDING BOILING WATER ONLY

A Valuable Evening Meal

"I used it with a patient I had under close observation, **the result was marvellous.** She has now had three large tins, and **has not been so well for some years.** I gave it only at night, an hour before bedtime, and **though only taken once in twenty-four hours she has gained over six pounds in weight,** while previously she was losing daily. It certainly is **a most satisfactory preparation."**

L.R.C.P., L.R.C.S.

Excellent for the Gouty

"I am using it myself and find it a good food. I think it is an **excellent supper dish for a gouty man, and I sleep well** after taking it."

. . . . . . M.D.

Promotes Refreshing Sleep

"I have used the "Allenburys" Diet at night with considerable benefit. I find it **sustaining and comforting,** and **sleep much better** after taking it."

. . . . . . M.D. (Lond.)

Quite *distinct* from the "Allenburys" Foods for Infants.

The "Allenburys" DIET is made from pure, rich full-cream milk and whole wheat, both ingredients being partially pancreatised during the process of manufacture. The "Allenburys" DIET is a complete food chiefly intended for Adults, and is an essential nutrient for **Invalids, Dyspeptics** and **the Aged.** It is quickly prepared, exceptionally palatable, easily digested, and wholly nourishing.

Prices: In tins at 1/6, 3/- and 6/- each. A large sample sent free on request.

"DRY PEPTONOIDS" SOLUBLE (Carnrick & Co.)

Beef, Milk, and Wheat, Pre-digested,

presents an easily assimilated, highly concentrated, and well-balanced food. It contains 40 per cent. of protein in the form of peptones and albumoses and 47 per cent. of carbohydrates in the form of lactose, dextrose, and maltose. "DRY PEPTONOIDS" SOLUBLE is Palatable, easily administered, being soluble to a diffusible solution in all ordinary fluid media, and is completely absorbed. It is indicated as a nutrient in Gastro-Intestinal Disease, after Crisis, during Convalescence, and in all cases of Weak Digestion.

CARNRICK & CO., Limited, 183, Acton Vale, London, W.,
Will be pleased to send Samples and Literature Free of Charge to Medical Men.

'OXYNTIN'

HYDROCHLORIC ACID COMBINED WITH ALBUMIN.

Oxyntin contains 5 % by weight of Hydrochloric Acid (absolute HCl.), in combination with albumin, the acid loosely bound to the protein. Ten grains of the Oxyntin therefore represent 5 minims of Acidi Hydrochlor dil. B.P.

Oxyntin is readily miscible with water, to which it imparts but a slightly acidulous taste, markedly devoid of the characteristics of even largely diluted free hydrochloric acid. Oxyntin therefore presents an extremely convenient means of administering hydrochloric acid in pernicious anæmia and disorders of digestion where the object is to increase the acid-percentage of the gastric content.

DOSE: 5 to 15 grains.

Supplied to the Medical Profession in 1 oz. bottles at 2/6 each.

'ENZYMOL'

A SURGICAL SOLVENT AND ANTISEPTIC.

AN EXTRACT OF THE GASTRIC GLAND OBTAINED BY DIRECT SOLUTION, ESPECIALLY PREPARED FOR EXTERNAL APPLICATION.

'Enzymol' dissolves all septic matter, corrects offensive odours, and imparts a healthy stimulus to the affected surface.

'Enzymol' is potent and entirely painless as a solvent, and is without action upon the normal tissue. It may be freely applied to all surfaces and cavities from which it is desired to remove dead tissue, pus, etc. 'Enzymol' will be found successful as a solvent in affections of the aural and nasal cavities, for dissolving coagula in the bladder, etc.

'Enzymol' is now being used on soldiers whose wounds are difficult to heal, especially those men who have foul smelling wounds.

'Enzymol,' simply by physiological action, converts morbid tissue and pus into a soluble form, which is thus readily removed by the ordinary methods of irrigation or washing.

Supplied to the Medical Profession in 4 oz. bottles, at 2/2 each.

Carthaginian mosaic portrait of Virgil, in glass and marble tesseræ. The poet holds on his knee a roll of papyrus, inscribed with lines from the Æneid. On his right stands Clio, the Muse of History; on his left, Melpomene with a tragic mask. The page-decoration is copied from the embroidery on the girdle or sash of Melpomene. Date, circa A.D. 200-400.

COPYRIGHT

Lysol

of all manufactures

completely Superseded by an ALL-BRITISH Antiseptic certified of Higher Disinfecting Value

TOXOL

Manufactured by Boots Pure Drug Co., Ltd.

Responding to the desire of the Medical Profession to discard preparations paying tribute to the enemies of this country, the laboratory staff of Boots, *the* Chemists (consisting of some 30 highly-trained analysts), perfected TOXOL, which is identical in all but name with "Lysol" as formerly imported from Herren Schulke & Mayr of Hamburg—a solution of cresols in a saponaceous medium—and superior in strength of disinfecting power.

TOXOL is pronounced by medical men who are using it to have all the qualities of "Lysol," and is certified on high authority to excel *all* samples of "Lysol" in disinfecting co-efficient.

Copy of Report by Dr. SAMUEL RIDEAL, joint-originator of the RIDEAL-WALKER Co-efficiency Test. November 16, 1914.

"I have purchased at one of your branches samples of TOXOL, and my results on examination confirm your labelled strength that it is two and a half times as powerful as Phenol, and it is higher than all samples of 'Lysol' I have examined." *(Signed)* SAMUEL RIDEAL.

The following are extracts from the letters of Medical Men who have already used TOXOL to replace "Lysol":—

"It seems to be in every way quite satisfactory and an excellent substitute for 'Lysol.'"

"Very glad to test and prove that English science is as good as that of the Barbarians. It would be a good thing to circularise the profession with a list of alien enemies' products."

"I tried it on a septic finger and found it all you stated it to be."

"TOXOL is very satisfactory. The medical profession ought to feel grateful to Sir Jesse Boot for replacing a German article in such a prompt and satisfactory manner."

"Am using sample and I am so pleased with it that I shall continue to use TOXOL in future."

"An excellent preparation. I obtained 'Lysol' many times from Hamburg before any English chemist would stock it, so am interested in your venture."

"Dr. —— is pleased to see an English manufacturer superseding a German product, and he will give his support to such a company as will do this."

"Many thanks; have used solutions of TOXOL in various strengths for numerous minor surgical cases with most satisfactory results."

"Will give TOXOL a trial. Am much interested in finding that your firm has succeeded in making a preparation in England of a German make like 'Lysol.' It is much more efficient than the German."

"Superior to 'Lysol' as far as I have tried it."

Samples of TOXOL will be delivered free on application to Medical Men who have not yet tested it.

TOXOL is sold in 6½d., 11d., 1s. 7d., *and* 2s. 9d. *bottles at all branches of*

THE WAR AND CARDIAC THERAPY

THE President of the General Medical Council recently called attention to the great shortage of Doctors and Nurses owing to the War.

How does this shortage affect Cardiac Therapy?

1. The busy, and often overworked, practitioner is with the greatest difficulty able to devote the same time and attention to the case as in pre-war times.
2. Owing to many Continental Spas being closed to the British visitor, Home Hydros are overcrowded and only at the disposal of a limited number of patients.
3. The enormously increased demands on Nursing Homes have placed them out of the question for patients of moderate means.

Under these circumstances, the busy medical practitioner will find it convenient to fall back upon Digitalis Medication and Home Treatment to safeguard the patient from recurring attacks of Asystole.

Digitalis Medication is a safe and practical method of preventive treatment well within the means of every patient.

Recent advances in Cardiac Pathology have drawn attention to the fact that if an Invariable preparation of Digitaline be given to a patient whose heart is comparatively regular, no untoward results occur; on the contrary, the Cardio-vascular system will be braced up, attacks of heart failure warded off, and the comfort of the patient so much increased that complaints will be made should the treatment be interrupted for any length of time.

The great difficulty of Digitalis Medication lies in the choice of a standard preparation of invariable dosage, for it is essential that the physiological activity of the drug taken by the patient should be known. Most preparations, especially the Tinctures, vary in strength.

Nativelle's Digitaline is a definite and invariable preparation which overcomes all difficulties, and as it is supplied in the form of small granules, it is most convenient. This preparation has been for many years one of the best known Cardiac remedies, a practical proof of the value of the drug.

The chemical reactions of Nativelle's Crystallised Digitaline are similar to those of Digitoxine of the French Codex, and whereas Digitoxine is anhydrous, Nativelle's Crystallised Digitaline is a hydrated derivative; it is less toxic than Digitoxine and its action is quicker and more regular.

Nativelle's Crystallised Digitaline is assayed physiologically, which accounts for the uniform results obtained by its use in therapeutics.

While small doses of Digitalis have no appreciable action on the healthy cardiac muscle, they have a very decided tonic effect on the failing heart.

It will be found by experience that the dose of Nativelle's Digitaline required varies with the individual. Some patients will remain perfectly comfortable on one granule of 1/600th of a grain every third night, others will require a granule every other night, or even every night.

In each case the minimum dose required to keep the patient comfortable should be ascertained, and once this has been learnt the treatment may be continued with very little alteration for months.

If this be done, the patient who has seemed, during an attack of asystole, to be in the very jaws of death, returns to a state of comparative health.

The symptoms, so distressing both to the patient and to his friends, abate, the rapid irregular pulse is steadied, diuresis increases, the œdema disappears, the dyspnœa vanishes, and the cyanosed lips regain their normal hue.

A Sample of these Granules will be sent free to any registered member of the Medical Profession on demand. Also particulars of other uses and doses of Nativelle's Digitaline.

GOLD MEDAL, INTERNATIONAL CONGRESS OF MEDICINE, LONDON, 1913.

MIST. DAMIANÆ CO. (HEWLETT'S).

MIST. DAMIANÆ CO. (Hewlett's) will be found to possess all the properties of Damiana, viz:—Its alterative effects on the alimentary canal and tonic action upon the brain and nervous system generally. It is a well-known fact that exhaustion of the organs and tissues, neurasthenia, and premature decay, are far more prevalent at the present day than ever before. The causes are numerous and complex, but, perhaps, the principal reason is that multitudes have to toil harder with their brains than any previous race. The resulting cerebral anæmia is, therefore, one of the most general complaints in modern life. Not only is it found amongst the professional literary men, but busy merchants and overworked scholars are equally the subjects of enfeebled nerve power and deficient vitality.

In all these various forms of loss of nerve power MIST. DAMIANÆ CO. (Hewlett's) is a powerful remedy, relieving the exhaustion and conferring renewed capacity for mental and physical endurance.

As a nerve tonic and brain stimulant it is unequalled, and its invigorating properties will be found invaluable in many diseases where there is great depression and exhaustion. In paraplegia, hemiplegia, and partial paralysis, it is particularly indicated, and may be suitably and satisfactorily employed wherever a powerful nerve stimulant and restorative are required.

Dose—One or Two Drachms in Water.

MEDICAL OPINIONS.

"I have tried your Mist. Damianæ Co. considerably in the dyspepsia of commencing phthisis, and can very strongly recommend its use in those cases. It soothes the stomach wonderfully, and enables the patient to take more food whilst acting as a powerful stimulant in relieving exhaustion."—Yours faithfully, W. H. B——, B.A. (Cantab.), M.R.C.S., L.S.A.

THE MEDICAL ANNUAL.—"Damianæ is not used so frequently in this country as in America, where its value as a tonic for Neurasthenia is well known. Messrs. HEWLETT & SON put up a very excellent preparation of this drug, combined with Nux Vomica and simple aromatics and bitters, which is valuable for dispensing, and yields very satisfactory results in treatment."—1898.

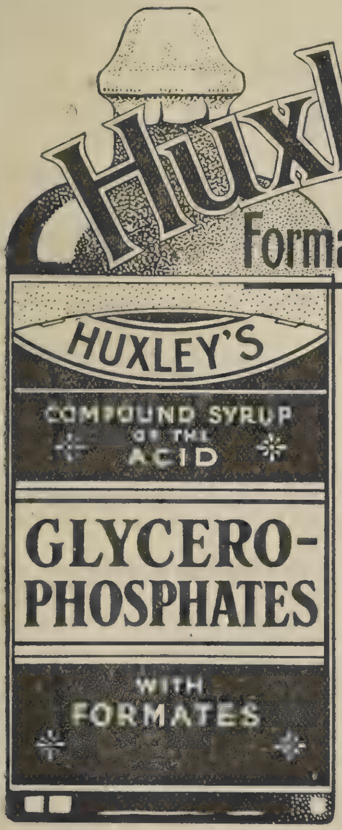
Dr. M——, R.N., writes:— "Farnham (Hants.), Sept. 1903.

"I have frequently prescribed your Mist. Damianæ Co. and proved it efficient in treating Neurasthenia."

PRICE 11/- per lb. Packed in 10-oz., 22-oz., 40-oz., and 90-oz. Bottles.

Introduced and Prepared only by—

C. J. HEWLETT & SON, LTD., 35 to 42, Charlotte St., LONDON, E.C.



Huxley's Syrup

Formates with Glycero-Phosphates

A bright cherry-coloured syrup, flavoured with Seville orange peel.

Contains:—Acid Glycero-phosphates and Formates of Lime, Soda, Potash, Iron, and Manganese (5 grains in 1 drachm) **with** *or* **without** *Strychnine Glycero-Phosph.* $\frac{1}{120}$*-gr.*

The Formates have general tonic and stimulant effects, especially noticeable when used in conjunction with the glycero-phosphates in

NEURASTHENOID or NEURASTHENIC STATES

or in abnormal fatigue from over-exertion, mental or physical.

Original bottles, ½-lb. or 1-lb. Free sample to Profession.

ANGLO-AMERICAN PHARMACEUTICAL COMPANY, Ltd., Croydon.

Bananina

A NATURAL Health Food, Highly Nutritive, Easily Digested

There can be no doubt of the nutritious character of Banana Flour. The starch in it is peculiarly easy of solution and digestion in the alkaline digestive juices of the body. Banana Flour is readily dissolved, for example, by saliva. It is eminently the food **for those of weak or impaired digestion.**

"BANANINA" possesses all the properties of Perfect Food combined with pleasant appearance and flavour when made up as directed. It contains the requisite amount of Nitrogen Carbon Fats and Mineral Salts in a form easy of digestion and assimilation.

"BANANINA" is richer in proteid than Foods with Wheat Flour as a basis, and it also contains more fatty matter, consequently its nutritive value is decidedly higher than that of Wheaten Flour.

As a source of energy and material for tissue repair, **"BANANINA"** stands above all other foods. By reason of its fruity nature it is anti-scorbutic. When prepared as per directions it is a **pre-digested** food for infants.

"BANANINA" has already received the endorsement of the Medical Faculty and Professional journals.

APPLEBY'S PURE Barley Flour

Unexcelled in purity and quality. Specially treated so that it is perfectly soluble, a particularly important point. Makes a highly nutritious food or refreshing and cooling beverage.

A point of importance, and one that you will fully appreciate, is that **"BANANINA"** and **APPLEBY'S "PURE" BARLEY FLOUR have not been chemically treated**—thus **all** the **natural** food properties are retained. Equally valuable in Nursery, Sickroom, and Kitchen.

We will gladly send any Doctor a testing sample so that he can form his own judgment.

BANANA BREAD FLOUR FOOD LIMITED,
Cereal Court, 16, Brunswick Street, **LIVERPOOL.**

UNIVERSITY OF MANCHESTER.

FACULTY OF MEDICINE.

The **WINTER SESSION** commences on October 7th.

The Faculty comprises 18 Professors and about 78 Lecturers, Assistant Lecturers, and Demonstrators.

The Laboratories and Museums afford every facility to Students and Graduates for Practical Instruction, as well as for Original Research.

SCOPE OF INSTRUCTION.

Complete Courses of Instruction are offered for the Examinations of the University of Manchester, and also for the Examinations of other Examining Bodies in the United Kingdom.

In the Dental Department Complete Courses are given preparing for the Degrees and Diploma in Dentistry granted by the University, as well as for the Diploma of the Royal College of Surgeons of England and other Dental Diplomas.

The Public Health Laboratories are situated at a short distance from the University. The fullest opportunities are offered to Graduates and others in preparation for the Diplomas in Public Health and Veterinary State Medicine, and for Special Certificates in School Hygiene and Factory Hygiene.

DEGREES AND DIPLOMAS CONFERRED BY THE UNIVERSITY.

OPPORTUNITIES FOR CLINICAL STUDY.

ROYAL INFIRMARY AND OTHER HOSPITALS.

The Clinical Instruction is given in the new Royal Infirmary, opened in 1909 on a site near to the Medical School. It is provided with every modern requirement for the treatment of the sick and the investigation of disease. Instruction in Special Subjects is given in other Hospitals associated with the University. A large number of beds in the General and in the Special Hospitals are available, thus affording unrivalled opportunities for Clinical Study.

1. The Manchester Royal Infirmary.	736 beds.
2. The St. Mary's Hospitals for Women and Children.	181 beds.
3. Manchester Children's Hospital.	188 beds.
4. Manchester Royal Eye Hospital.	132 beds.
5. Manchester Northern Hospital for Women and Children.	70 beds.
6. Fever Hospital for Infectious Diseases.	600 beds.
7. Special Hospitals for Diseases of the Ear, Throat and Chest, Skin, and the Christie Cancer Hospital.	234 beds.
8. Dental Hospital of Manchester.	
9. Ancoats Hospital.	119 beds.
10. Salford Royal Hospital.	208 beds.

HOSPITAL APPOINTMENTS.

In consequence of the large number of Hospitals associated with, or in the vicinity of, the University, exceptional opportunities are offered to Graduates to obtain Resident Hospital Appointments.

SCHOLARSHIPS, EXHIBITIONS, AND PRIZES.

Two Open Entrance Scholarships, each of the value of £100, are offered yearly in July. In addition, the Dreschfeld Scholarship of £30 per annum, and other Entrance Scholarships of the value of £30 to £40 a year for two or three years, are also tenable in the Medical Faculty. Amongst other Scholarships the following are also offered for Encouragement of Medical Study.

1. Two Dauntesey Scholarships of the value of £45 and £35.
2. Platt Physiological Scholarship (£50 for two years).
3. Leech Fellowship (£100).

INVERNITH SANATORIUM, COLINSBURGH, FIFE, SCOTLAND.

(Licensed under the Inebriates Acts.) FOR GENTLEMEN ONLY.

(Under the direction of an Advisory Council of eminent Medical Men.)

NEURASTHENIA is treated on approved principles, and there are Open-air Shelters in the grounds for suitable cases.

INEBRIETY and **NARCOMANIA** are treated on definite medical lines, and the most approved scientific means are employed in the curative treatment. The Resident Medical Superintendents have each patient under their personal care and observation. The curative treatment is much aided by the healthy situation of the Sanatorium and by its isolation from temptation.

The Sanatorium stands 450 feet above the sea, faces south, and looks out over the Firth of Forth. The climate is dry and bracing. All out-door and in-door sports. First-class private golf course. Excellent mixed shooting over 1600 acres, fishing, tennis, gardening, carpentry, &c. Billiard room (two tables), music room, large private library.

References to leading physicians in the chief centres given on application.

For all particulars of Invernith Sanatorium, Ltd., apply to the *Resident Medical Superintendent*, W. H. BRYCE, M.B., C.M.

NORWOOD SANATORIUM, LTD.,

REMOVED TO

THE MANSION, BECKENHAM PARK, KENT.

UNDER A COMMITTEE OF WELL-KNOWN MEDICAL MEN whose names will be supplied to any Member of the Profession on application to the Resident Medical Superintendent. The object is to apply to the treatment of Alcoholic and Drug Inebriety all available knowledge, and, by accurate observation and record of cases, to extend that knowledge, and place the therapeutics of Inebriety upon a definite scientific basis. The treatment is of such a nature that the restrictions common to Retreats need not be enforced. In many cases a residence of six weeks is sufficient. The Sanatorium consists of a large family mansion, recently redecorated and brought up-to-date in all respects. It is situated in a large and beautifully wooded private park in near proximity to London. All information to be obtained from the Resident Medical Superintendent. Consultations at 13, Welbeck-street, W., every afternoon *by appointment.*

Telegrams: "NOROTORIUM, BECKENHAM." Resident Medical Superintendent: FRANCIS HARE, M.D. *Telephone:* 648 BROMLEY.

Telegrams: "Instruments, London." Telephone: 5240 City.

Locum Tenens wanted immediately.—Mr. Percival Turner is in immediate want of several reliable Gentlemen with satisfactory credentials to fill vacancies caused by the War and otherwise.—Apply, personally if possible, to Percival Turner, 4, Adam-street, Strand, London, W.C. Telephone 3399 Central.

Locum Tenens urgently required.—Messrs. ARNOLD and SONS require several reliable gentlemen to complete their staff.—Apply, Transfer Department, 6, Giltspur-street, London, E.C. (opposite St. Bartholomew's Hospital). Telephone: 5240 City. Telegrams: "Instruments, London."

Gold Coast Colony, West Africa.—Two immediate vacancies for MEDICAL OFFICERS on Government Railway, fifty miles from Coast, for senior men with Tropical qualifications and experience. Service on the Coast six to eight months. Salary on basis of £720 per annum, and quarters. Return passage.—Apply to J. A. Reaside, Watergate House, Adelphi, W.C.

Wanted immediately (for period of war) for Group of Collieries and Iron Works in South Wales, reliable qualified SURGEON to examine and report upon injured workmen under Workmen's Compensation Acts, and give evidence in court when necessary. Apply, with full particulars, to the Secretary, Ebbw Vale Steel Iron & Coal Co., Ltd., Ebbw Vale.

Pathological Work.—The Coöperation of an experienced PATHOLOGIST is required in a small Clinical Laboratory (Private). The work would not necessarily interfere with private practice or clinical engagements. One familiar with technique would be preferred, but an earnest and reliable worker would be welcomed and a pecuniary share arranged.—Address, No. 440, THE LANCET Office, 423, Strand, W.C.

M.B., Ch.B., and a candidate for D.P.H., wants an appointment as a LOCUM or a RESIDENT in a Hospital near any University Town. Whole-time or part-time service. Disengaged in early July. Excellent testimonials of obtaining honours, and a good experience as a resident, an anæsthetist, and in X-ray work.—Address, No. 443, THE LANCET Office, 423, Strand, W.C.

Holiday Exchange.—M.D., D.P.H., Severn Valley. Large well-stocked garden, tennis court. Easy practice. Would exchange, London or Seaside, three weeks in August.—Address, No. 444, THE LANCET Office, 423, Strand, W.C.

A fully qualified Medical Student will accept PART EMPLOYMENT in Town. Previous experience.—Address, No. 442, THE LANCET Office, 423, Strand, W.C.

Lady Dispenser required 19th July. £6 per month, out-door.—Apply, with testimonials, to Dr. Martin, Chelmsford.

Wanted, Dispenser and Bookkeeper, out-door. Private practice. Permanency to suitable person.—Address, stating salary required, to No. 446, THE LANCET Office, 423, Strand, W.C.

Certificated Masseuse, Diplomée Southport Physical Training College, desires Visiting, Massage, or Remedial Work at Hospital, Surrey or London, for September. Good references. Experience.—Address, Miss Richardson, Tormead, Cranley-road, Guildford.

Medical Debts purchased outright for cash (any locality). Good price quoted on receipt of List of Debts. Ordinary collections undertaken if preferred.—Silvester, Medical Accountant, 66½, Corporation-street, Birmingham.

M.D., F.R.C.S.E., married, desires PARTNERSHIP to release man for War Service. Country Town or Suburb, with Surgical Hospital appointment preferred.—Address, No. 441, THE LANCET Office, 423, Strand, W.C.

Panel and Working-class Practice wanted to purchase, to produce £1000 a year or more. Must be situated in London, not suburbs.—Replies in strict confidence to No. 445, THE LANCET Office, 423, Strand, W.C.

Practice wanted (non-panel) in Kensington or Bayswater, by experienced well-qualified man with good panel. Would assist man retiring or away.—Address, No. 447, THE LANCET Office, 423, Strand, W.C.

Partnership.—Lady (trained nurse), proprietress of a large and beautifully furnished Convalescent Home, Bournemouth, desires to meet Lady or Gentleman (M.D. preferred but not essential) to join her. Amount of capital investment arranged at interview. Splendid prospects. Best medical support.—Confidential details from Deverell, 3, Waterloo-road, London, S.E.

For Disposal.—A really good Practice is not always to be had directly, but Mr. PERCIVAL TURNER (with thirty-six years' personal experience) can generally offer applicants something suitable on being furnished with details of their requirements. Nearly all the best Practices are Sold by him without being advertised.—Full information free of charge on application, personally or by letter, to 4, Adam-street, Adelphi, Strand, W.C.

Urgent.—Near London.—Unopposed old-established PRACTICE within twenty miles on rail. No opposition for four miles. Easily worked. Income £800 to £900, and increasing. Price only £800; £400 down.—Apply, No. 5626, care of Mr. Percival Turner, 4, Adam-street, Strand, W.C.

War Notice.—Messrs. Arnold & Sons have made special arrangements which will enable Members of the Profession who are serving as Officers at the front or whose Practices are affected by the War to transfer all their obligations, business or domestic; they are also willing to undertake and supervise all matters appertaining thereto, such as Payment of Rents, Premiums, School Fees, Allowances to Dependents, &c., and the efficient conduct of the Practices during their absence.—Address, in confidence, Arnold & Sons, Transfer Department, 6, Giltspur-street, London, E.C.

West End Practice.—No premium.—An easily worked good-class connexion, worth about £300 a year. No dispensing or panel. Fees from 5s. upwards. Excellent house in good position, rent £75. Will be given to purchaser of complete outfit of furniture, &c., as it stands valued at £500.—Apply, No. 5804, care of Mr. Percival Turner, 4, Adam-street, Strand, W.C.

Practices and Partnerships.—When purchasing either the importance of a careful investigation of the Vendor's books should be borne in mind. Messrs. LEE & MARTIN, of 93, Hall-road, Handsworth, Birmingham, have a Department specially for this work, and only Chartered Accountants are employed. Charges moderate and efficiency guaranteed.

Cornwall.—£500 a year, in Seaside Resort. Easily worked. No horse. Great scope. Rent £35. Panel about £220. Vendor retiring. Easy terms of purchase.—Apply No. 5798, care of Mr. Percival Turner, 4, Adam-street, Strand, W.C.

For Sale.—Partnership.—Half Share, worth £890 per annum in old-established mixed family country Practice, small panel, near London. Good house and garden; rent £80. Premium two years' purchase.—Apply by letter to "A," care of Messrs. Willows & Co., Ltd., 40, Aldersgate-street, E.C. No agents.

London Suburbs.—Nearly £1000 a year.—General Middle-class PRACTICE in S.W. Suburb. Vendor joining army. Visits 2s. to 5s. Very small panel. Small house; rent £42. Premium can be arranged.—Apply, No. 5774, care of Mr. Percival Turner, 4, Adam-street, Strand, W.C.

To be disposed of, Nursing Home for Weir-Mitchell and general cases, with patients. Fine rooms. Large grounds. Healthy district. Easy distance for London doctors.—Write "Treatment," care of J. W. Vickers & Co., Limited, 5, Nicholas-lane, E.C.

To Purchasers.—Do not buy any Practice or Partnership without an investigation into books and other inquiries by an expert specially competent to conduct the same. Thirty-six years' personal attention to such inquiries has given Mr. PERCIVAL TURNER an unique ability to advise in all cases. Terms and full particulars free on application to 4, Adam-street, Strand, London, W.C. Telephone: 3399 Central. Telegrams: Epsomian, London.

Death Vacancy. — East County. — £850 a year. Vendor killed on active service. Pleasant residential Country Town, near sea; station close. No panel. Appointments nearly £200. Excellent introduction by widow and locum. All kinds of sport. Nice roomy house.—Apply, No. 5796, care of Mr. Percival Turner, 4, Adam-street, Strand, W.C.

For Disposal, Practices or Partner-SHIPS.—Messrs. ARNOLD & SONS, Surgical Instrument Manufacturers, have been instructed to privately dispose of a large number of really good Practices and Partnerships. Gentlemen are requested to state their requirements and amount of capital available. No charge to purchasers.—Address, Arnold & Sons, Transfer Department, 6, Giltspur-street, London, E.C. (opposite St. Bartholomew's Hospital).

Urgent.—Unopposed West County. —Nearly £1000 a year, in picturesque residential district. No opposition. Plenty of society. Good family house, garden, orchard, &c. Easily worked. Insurance over £300 a year. Vendor joining army. Premium only £950, partly instalments.—Apply, No. 5772, care of Mr. Percival Turner, 4, Adam-street, Strand, W.C.

For Disposal, Practice of the late Dr. Albert Hilton (Surgeon Major, 1/9 Battalion Manchester Regiment, Territorials), situate in the populous manufacturing district of Ashton-under-Lyne, near Manchester. Private and panel (panel about 600), together with house, brougham, and trap.—Application to Messrs. Moss & Barker, Accountants, Market-place, Ashton, who will be pleased to answer inquiries.

Panel Practice.—Urgent Sale.—Easy terms.—Very old-established PRACTICE in North London, at present returning £400 to £500 a year, for Sale owing to illness. Receipts mostly from panel. Corner house. Open situation. Premium £400 or offers.—Apply, 5764, care of Mr. Percival Turner, 4, Adam-street, Strand, W.C.

North-West Counties. — Owing to illness of vendor, a good Middle-class PRACTICE in charming Town is for disposal. Average receipts £825; in 1914 £908. Fees 3s. 6d. to 5s. No appointments. Panel of 680. No dispensing. Motor kept. Commodious house. Very moderate premium.—Apply, Mr. J. A. Reaside, Watergate House, Adelphi, W.C.

South County.—Over £1000 a year. —Good-class increasing PRACTICE in a small Town within one hundred miles. Fees 3s. 6d. to 15s. Panel 900. Good house, and garden, lawn, &c.; rent £40. Vendor going on active service. Hunting, shooting, &c. Personally known and recommended.—Apply, No. 5779, care of Mr. Percival Turner, 4, Adam-street, Strand, W.C.

Death Vacancy. — Warwickshire.— Old established PRACTICE in same hands for thirty-six years. Receipts over £1100. Appointments £100. Panel 1820. Clean, prosperous growing town. Good house and garden, with separate surgery entrance; rent £70. Exceptional opportunity for active man.—Offers invited to Blundell & Rigby, Walter House, 418–422, Strand, London, W.C.

War Sale.—Over £600 a year, un-opposed, in beautiful Country district in West County. Station within three miles. Appointments over £250. Easily worked. Nice house and garden; rent £50. Premium only £450. Personally investigated and recommended.—No. 5761, care of Mr. Percival Turner, 4, Adam-street, Strand, W.C.

Bargain. — For immediate Sale, Middle-class General PRACTICE in healthy London Suburb. Established for twenty-five years. Income for last three years averages over £1400. Non-panel. One or two good appointments held; transferred or rebate allowed. Good corner house. Premium £1500.—Address, No. 434, THE LANCET Office, 423, Strand, W.C.

Urgent.—On the Thames.—Unusual opportunity offers to secure a very old established, easily worked, good-class PRACTICE of about £500 a year in a very favourite and rapidly growing resort on Upper Thames. No horse required. Charming riverside residence, large garden, tennis lawn, &c. Panel about £250. Vendor going on active service. Moderate premium from prompt buyer.—Apply, No. 5800, care of Mr. Percival Turner, 4, Adam-street, Strand, W.C.

A Bargain.—Country Practice of £400, including £250 of transferable appointments, in a Midland Town. Large old-fashioned house, well furnished; fine grounds, well planted. Low rental. Drugs and furniture included (which cost £200). Price inclusive £500.—Address, No. 439, THE LANCET Office, 423, Strand, W.C.

Bargain. — Practice, N. London. — Income £400. Panel 726, registered and growing. Rent £38. Large roomed convenient house, close to station and tube. Price, cash down, £350. No agents.—Address, No. 449, THE LANCET Office, 423, Strand, W.C.

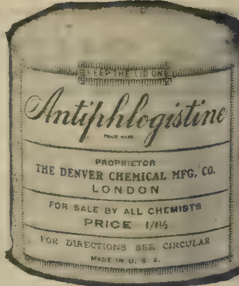
A Perfect Poultice-

physiologically active from the first moment of contact; physically clean, convenient, and agreeable to the most fastidious patient; protective to the most sensitive skin, which, on removal of poultice, even after 48 hours, is always in a normal, wholesome condition.



Directions:—Always heat in the original container by placing in hot water. Needless exposure to the air impairs its osmotic properties—on which its therapeutic action largely depends.

The foregoing briefly describes

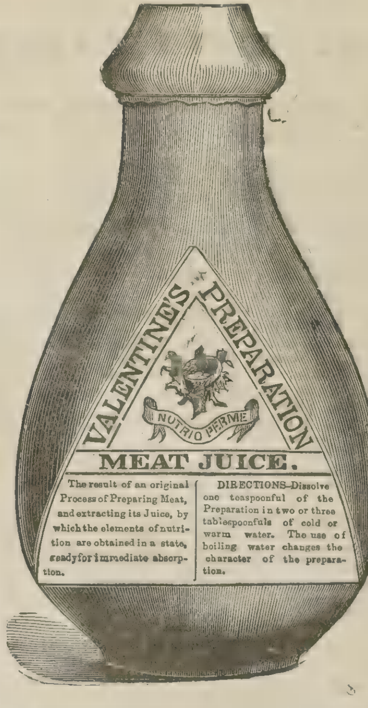
Antiphlogistine

which, for more than twenty years, among progressive physicians, has superseded the old-time, bacteria-breeding, soggy, uncleanly disagreeable flax-seed, bread-and-milk, and other unscientific, ineffective poultices; most of which, on removal, leave the skin softened to a degree bordering on, if not actually producing an abrasion with possible infection, later.

Physicians should WRITE "Antiphlogistine" to AVOID "substitutes."

"There's only ONE Antiphlogistine."

THE DENVER CHEMICAL MFG. CO., BOW, LONDON, E.



VALENTINE'S PREPARATION
NUTRIO PERME
MEAT JUICE.
The result of an original Process of Preparing Meat, and extracting its Juice, by which the elements of nutrition are obtained in a state, ready for immediate absorption.
DIRECTIONS—Dissolve one teaspoonful of the Preparation in two or three tablespoonfuls of cold or warm water. The use of boiling water changes the character of the preparation.

Valentine's Meat-Juice

In **Diarrhoea, Dysentery** and **Cholera Infantum** where it is **Essential** to **Conserve** the **Weakened Vital Forces** without **Irritating** the **Digestive Organs, Valentine's Meat-Juice** demonstrates its **Ease** of **Assimilation** and **Power** to **Sustain** and **Strengthen.**

W. B. Scranton, M. D., *Medical Superintendent Korean Mission Methodist Episcopal Church, Seoul, Korea:* "A most excellent use I frequently put VALENTINE'S MEAT-JUICE to is tiding Babies through Cholera Morbus and the Wasting Diseases incident to Summer and Inanition. It acts at once, and many a crisis has been passed safely by my patients, through the agency of VALENTINE'S MEAT-JUICE. It has also been of great value in my practice in the Far East in the treatment of that form of Summer Diarrhoea known as Sprue, where it tides the patients over until they can get to a better climate."

F. E. Gordon, M. D., *Anniston, Alabama:* "My baby took VALENTINE'S MEAT-JUICE with relish and with great benefit, and to its sustaining properties I think her recovery from one of the worst cases of Entero-Colitis I ever saw was largely due."

For Sale by European and American Chemists and Druggists.

VALENTINE'S MEAT-JUICE COMPANY,
D 115 **RICHMOND, VIRGINIA, U. S. A.**

NATURAL MINERAL WATERS.

RICHARD DAVIS continues to receive Fresh Supplies from FRANCE, ITALY and SPAIN.

20, MADDOX STREET, LONDON, W.

The NATURAL

SPANISH APERIENT WATER

RUBINAT-LLORACH.

[FROM THE LERIDA SPRING, SPAIN—LEASED BY A FRENCH COMPANY.]

(Hydragogue, Purgative, and Cholagogue.)

The BRITISH MEDICAL JOURNAL says:—

"Examination showed it to contain no less than *10·3 parts of anhydrous salts in 100 parts by measure*, the principal constituent being sodium sulphate; magnesium sulphate, sodium chloride, and calcium sulphate were present in much smaller quantity. The analysis represents the dissolved salts as follows (grams per litre being here converted into grains per fluid ounce):

Sodium sulphate	42·16 grains.	Calcium sulphate	0·85 grains.
Potassium sulphate... ...	0·10 ,,	Sodium chloride	0·90 ,,
Magnesium sulphate ...	1·43 ,,	Silica, alumina, iron, &c..	0·02 ,,

In one fluid ounce.

(42·16 grains of anhydrous sodium sulphate represents 95·7 grains of the usual crystallised salt, or 'Glauber's salt.')

In view of the large amount of purgative salts present, *a comparatively small dose suffices, a wineglassful*" (fasting).

Administration: 90, AVENUE NIEL, PARIS.

FREE SAMPLE ON APPLICATION.

OF ALL CHEMISTS, DRUG STORES, &c.

THROUGHOUT THE UNITED KINGDOM.

MARTINDALE'S WAR LIST

FOR THE TREATMENT OF WOUNDS.

AMYL NITRITE CAPSULES, as manufactured for over half a century. The promptest physiological remedy for relief of hæmorrhage and a valuable aid in warding off and arresting fainting attacks. As exported all over the world. In boxes of 12 glass capsules, conveniently cased in cotton wool and silk, per doz. boxes 27/-.

AROMATIC AMMONIA.—Smelling Salts in capsule form for inhalation. Boxes of four, encased similarly to the above, per dozen 9/- ; boxes of 12, per dozen 27/-.

"BORSAL."—A dusting powder for applying plentifully to wounds which can be surgically opened. In convenient tin dredgers, per dozen 24/-.

CRESOL PASTE 20%.—A useful adjuvant especially for the deeper parts of the wound. Wounds so treated will remain aseptic.

CRESOL PASTE is supplied in "Collapsubes" of pure tin, with convenient long nozzle, per dozen 4/6. These tubes are filled at the special request of eminent Surgeons (see "Hunterian Oration," Feb. 15th, 1915), with a Pure Re-distilled Cresol in a special Ointment basis, found by bacteriological, pharmacological, and clinical trials to be the best for gunshot and shrapnel wounds.

IODINE STERILISED CAPSULES.—Many surgeons still adhere to Iodine as a first-aid treatment. Iodine Solution is not portable and cannot be so easily introduced into a cavity. To meet demand, however, we supply glass capsules completely encased in wool and absorbent casing. There is nothing complicated about our Capsules, no thinking which end to use—the directions are, smash it, use all of it.

In three forms :—1. In boxes of 8, each 2/3. 2. In metal tubes, boxes of 12 each 3/-. 3. In highly finished screw-cap white metal tubes, with a small piece of lint, per dozen 7/-.

MASTICH SOLUTION.—This has been advised by some surgeons as an antiseptic dressing to wounds. It is stated to be a harmless disinfectant by arresting the micro-organisms on the skin, &c., where applied, virtually entangling them. Its action is rapid and quite painless. For further details see the "Extra Pharmacopœia," 16th Edition, Volume I., p. 832. Original 4 oz. bottles, per dozen 36/-.

FOR THE TREATMENT OF AND THE PREVENTION OF VERMIN OF ALL DESCRIPTIONS.

We have prepared numerous useful Ointments and Solutions for combating this evil. The following is a brief selection :—

MERCURIAL POWDER, in dredgers containing diluted Ammoniated Mercurial Powder, for applying to the skin. Per dozen 18/-.

This powder is also used in the form of Sachets for wearing back and front. The Mercury in this case operates by its slow evaporation, thereby fumigating the parts by which it is applied. Sachets per dozen 12/-.

MOSKITIN CREAM.—An Ointment containing a blend of numerous Essential Oils similar to the well-known "Moskitin" in liquid form. Collapsible tubes are rather more convenient for carrying than liquids. Per dozen 6/- and 12/-.

PETROLEUM INSECTICIDE.—An effective preparation for removing lice, fleas, flies, &c., both destroying them and preventing their further attack, and thereby acting as a prophylactic in many forms of infective disease—typhoid, typhus, diarrhœa, consumption, &c. This can be used like ordinary soap for washing purposes. If a little be dried into the clothes, vermin will not approach clothes thus treated. A similar effect is procured by rubbing a little of the insecticide over the skin. Large tins, per dozen 12/-.

SULPHUR DREDGERS.—Sulphur is an invaluable insecticide, warding off all forms of vermin. The method of use is to dust into the creases of the clothes and to apply to the skin where necessary. Per dozen 8/-.

STAVESACRE OINTMENT.—A standard remedy for nits, which has the reputation for not only removing the vermin, but also killing the ova. Per dozen collapsible tubes 24/-

FOR PREVENTING POISONING BY GAS.

RESPIRATORS.—Form I.–Khaki-coloured gauze and wool pads impregnated with Sodium Thiosulphate. Per doz. 12/-

Form II.—Bag-shaped, of flannel, to fit over the nose and mouth, with a supply of impregnated wool. Per dozen, 12/-.

Form III.—Enclosing the face entirely, with mica slip for eyes. Per dozen 36/-.

Form IV.—Official form. Of cotton waste impregnated, enclosed in netting. Per dozen 24/-.

GOGGLES.—Fitted with glass or with non-inflammable transparent material. Prices each 3/- and 4/-.

LANOLIN CREAM.—It has been suggested to rub over the eyes, nose, and lips with this preparation to form a protective covering. ***It is strongly advised that this preparation should be used in conjunction with all Thiosulphate respirators.*** Dozen 24/-.

We are making a special feature of the manufacture of ORGANIC CHEMICALS hitherto obtained from Germany, and would welcome enquiries.

TRADE MARK.

W. MARTINDALE, Manufacturing Chemist,
